KEY TERMS AND DEFINITIONS

M

Dead Reckoning: A localization method that consists of calculating the current location as the result of a displacement function applied to the previous location.

Fingerprinting: A localization method where the current location is determined by measuring the local characteristics of one or more signals (usually of electromagnetic nature) and comparing them with a set of values stored in a database. The database contains a map of signal values and their corresponding physical locations.

Inertial Measurement Unit (IMU): A sensing device that reacts to changes in its velocity (accelerometer) or orientation (gyroscope). When mounted on a rigid body, it allows measuring the acceleration or orientation of the body.

Landmark: A location characterized by specific values or patterns of sensor readings that can be used to uniquely identify the location during successive visits. Measured values can be specific to the local environment (e.g. electromagnetic signals), or related to how the location is accessed by the visitor (e.g. acceleration patterns observed when using a staircase).

Map Matching: The technique of matching location estimations coming from sensor readings with constraints or hints coming from a map of the environment.

Simultaneous Localization And Mapping (SLAM): A technique for localizing a person or object in an area and simultaneously building a map of the area by processing sensor reading data. Usually, the map is built and adjusted incrementally during multiple visits to the area, and localization accuracy improves during the map building process.

Step Detection: A method for automatically recognizing the walking steps of a pedestrian, usually by means of an IMU mounted on a device carried by the pedestrian.

Technological Innovation and Use in the Early Days of Camera Phone Photo Messaging

Jonathan Lillie

Loyola University, USA

INTRODUCTION

The introduction of picture taking and messaging capabilities to mobile phones is one of the four most significant and impactful innovations that mobile phones in general have offered to humanity in the last 25 years; the others being mobile telephony, text messaging, and mobile Internet access/services. Of course in making such a claim, one quickly runs into a morass of classification. After all, many mobile Internet behaviors are based in part on image sharing practices; and image sending piggybacks somewhat on the older texting platforms, both in terms of technology and behavior. The journey of camera phone use and image messaging – from early designs and strategies of phone manufactures to the wide diversity of practices that are observable today – is a classic example of technological innovation. And by “classic” I mean that innovation tends to never cease, especially with those technologies that are built on flexible platforms, or else where manufacturers have incentive to continually change the technology based on user innovation and practices. Such was the case when Nokia, and other handset companies, changed strategies (at least in part) after early user studies demonstrated that early camera phone adopters had different practices in mind than the companies did. Since that time, the innovation in mobile imaging practices has mostly been in the hands of user groups and social media companies.

This chapter presents a sketch of the early days of camera phone and MMS use. Since the main goal of the chapter is to review relevant literature, it does not address the contexts of camera phone use for any specific user group or region in any depth. However, rather than merely presenting the findings of the many excellent studies of camera phone users in the early and mid-2000s, I hope to also complement these studies, in part, by showing the role played by one of the main regional and global industry actors (Nokia) in shaping the technology and then responding to user trends and innovation. In the book *Everyday Innovators* (2004), which is largely devoted to research of user innovation with mobile phones, Alexandre Mallard of the Center for the Sociology of Innovation in Paris concludes that, “where users will behave creatively seems to be quite unpredictable!” (p. 42). Users, he continues, often reproduce the roles proscribed for them by industry, but they can also discover and champion new unintended uses, and enthusiast can sometimes even alter the hardware or software to essentially change what the technology can be used for. The studies reviewed in this chapter (focusing mostly on European and Asian countries) show that early camera phone users embraced the technology as a significantly enhanced form of the portable analog camera, which had a long history of cultural practice, as opposed to being more enthralled with photo messaging as industry had hoped.

Figure 1. Camera phone units as of 2005 and projection up to 2010

BACKGROUND

The Camera Phone and MMS: Industry Innovation and Marketing

The major mobile phone manufacturers started to market and sell their first camera phones in late 1999/early 2000. Just seven years later the number of camera phones surpassed the one billion mark (Figure 1). But the problem for the industry was not whether people would buy handsets, it was if people would use the new photo messaging features. Nokia along with many other European manufacturers and service providers wanted to create the next “killer app” for mobile technology, and were pushing for that to be a new standard called multimedia messaging service or MMS. Some industry players expected MMS to piggyback on the success of the SMS text-messaging platform. Over the previous decade Nokia had invested heavily in the design of SMS and the cellular platform that made it possible, the Global System for Mobile Communications (GSM). GSM was the second-generation, digital cellular system adopted by most European countries. The company’s success in the 1990s was due in part to its investment in SMS, which resulted in the technology’s seamless integration with its handsets. As

is well chronicled in the industry and academic literature, texting boomed in Europe propelled by 1990s youth culture. Though the industry did not anticipate the texting craze, it quickly responded “to capture these new uses and repackage them as fee-producing services” (Snowden, 2006, p. 112). So as the third generation (“3G”) cellular system was being developed to improve GSM with faster connections and enhanced services, Nokia (and other players) ensured that the new standard would include a photo/video messaging service commiserate with its plans for introducing camera phones by the end of the decade.

Nokia bet that new camera phone users would view MMS as SMS 2.0 (Loubser, 2005; Pohjola, O. P. and Kilkki, K., 2005), which they would not mind paying more money for due to the utility of sending and receiving multimedia content (Nokia, 1999). The company’s early market studies focused in on person-to-person and person-to-multiperson picture messaging, since these services were most like SMS and hence, they hoped, most likely to attract potential early adopters of MMS (Nokia, 1999). One of Nokia’s early user studies of MMS found that Internet downloads of pictures and other commercial media such as news alerts, travel info, and weather updates were also attractive to users and likely to be high revenue services. However,

Nokia's aggressive rollout of MMS phones in the early 2000s meant that many of these services, such as downloading commercial media from websites, were still in the development stage, while others like camera-to-camera photo messaging worked better on some service networks than on others.

One of the leading experts on the Nokia Company is Dan Steinbock of Shanghai Institute of Foreign Trade. In *The Nokia Revolution* (2001) Steinbock explains how Nokia also emerged as the global leader in mobile phone production in the 1990s because of its focus on innovation in marketing. When SMS-enabled phones started rolling out, the company applied Geoffrey Moore's theories of technology-adoption life cycles to new product designs and marketing campaigns aimed at targeted lifestyle groups such as "'poseurs,' 'trendsetters,' 'social contact seekers,' and 'high-fliers'" (Steinbock, 2001, p. 279). New downstream marketing innovations involved ad campaigns focused on these groups, artistic removable faceplates, monthly rollouts of new models, and new multi-model product categories. Nokia unveiled its first camera phone in 1999, which was a high-end model designed for business users. The company continued to help to develop the MMS technical standard while at the same time releasing mid-market camera phones like the 3650 model, its first camera phone sold in the United States in 2003. Having as many camera phones on the market as possible was essential if MMS was to take off on a large scale like SMS did. Commercials on TV and the company's websites depicted new MMS users discovering fun and creative uses of picture messaging with the latest handset models (see Lillie (2012) for analysis of Nokia's advertising during this period). Nokia had 28 percent of the global market by 2007, making it the largest manufacturer of camera phones (Taylor, 2007). By the end of the decade almost all Nokia models were equipped with cameras and MMS.

EARLY CAMERA PHONE USER STUDIES

A Nokia press release from 2003 illustrates the company's enthusiasm for MMS:

The depth of demand for MMS services is extremely good news for the industry ... Consumers really want MMS and, as operators are already discovering, people are as intrigued by and eager to use MMS as SMS.

However surveys of early use show that consumers were not as hyped for the new service. In the UK only 27 percent of camera phone owners had ever used MMS by 2003 (Continental Research, 2004). Across the Atlantic in the US, potential users were actually less interested in MMS in 2004 than in 2003 (Zelos Group, 2004). A mid-year 2006 US survey of camera phone imaging practices revealed phone-display picture viewing to be by far the most common use (72%) followed by saving pictures to a computer (33%), emailing pictures (31%), sent via MMS (28%), printed (13%), shared online (12%), and none of the above (17%) (Lyra Research, 2006). Studies in Asian countries also found that early uses tended to focus on the camera features as opposed to photo-sending. In Japan the first camera-embedded phone came out in 2000, but only four years later they were already a majority of all mobile phones (Okabe and Ito, 2006). Surveys of camera phone use in those early years showed that almost all users showed photos on the phone to others, while 50 percent reported "emailing" photos to friends and family (japan.internet.com, 2003). Just having an easy-to-use digital camera that was also handy for mobile telephony appeared to be what users were at first attracted to in the camera phone. Early on that simple but culturally and cognitively powerful add-on was the real killer app. Not MMS.

The early ethnographic studies of camera phone use confirmed that MMS was being used by some people for image sharing, mobile-to-mobile, but also showed that other uses of built-in cameras were far more common. One of the most frequently cited works from this early period is by Dr. Barbara Scifo (2005) of the University of Milan who applied focus groups and in-depth interviews to explore how teenagers and young adults in Italy were using camera phones. Based on the study, Scifo argued that the social uses of camera phone mostly fall into two categories. The first category is face-to-face interaction where fast viewing of saved photos added to conversation and the sharing of personal experience. The second category included the various uses of MMS. She argues that,

notwithstanding the [low] number of MMS messages that are being exchanged at present between those starting to use this new process of communication, there are already clear signals concerning the spread of a precise culture of communication and the birth of a new language (p. 5).

Three functional types of picture messaging were identified by Scifo. The first included MMS messages employed to induce an action by someone else. For example, I might send a photo – of myself with a pint at a local pub – to a friend as an invitation to join me. Informative messages, on the other hand, might show off my current vacation location or the first flower of spring in my front yard. Lastly, problem-solving messages, are used to reduce effort, costs, or solve immediate problems, such as taking a picture of the jacket I want for my birthday and sending it to my wife with the caption, “a not so subtle hint.” Scifo found that MMS messages are typically limited to conversations among friends and family, which is supported other studies in European and Asian countries (Kindberg, Spasojevic Fleck and Sellen, 2004; Okabe and Ito, 2006). “The camera-phone represents a new form of extension of one’s experience and memory,” Scifo concludes. “On the

socialization level, it represents a new communication resource that can be invested in one’s peer group and in one’s relationships” (p. 3).

In their review of the MMS-focused literature Kindberg, Spasojevic Fleck and Sellen note that the early studies sponsored by industry leaders, such as Hewlett-Packard and Nokia, observed how participants sent images “to increase or maintain group cohesion, express affection, support conversation, and tell stories” (2004, p. 1). A similar study by Battarbee and Kurvinen (2003) considered how users can develop creative personal styles in the way they use MMS, particularly in terms of the types of images sent and how these are used to communicate with friends and family. The authors note that although user innovation and experimentation is important in such creative communication, the designs of the handsets and services themselves are also vital.

“Technology enables these experiences, it defines what can and cannot be done,” the authors conclude. “Technology determines how simple and easy it is for people to co-presently collaborate in its use, and how in new situations, users negotiate new uses and meanings” (p. 7).

Most of the early camera phone user studies were conducted in European and Asian countries where – for a variety of cultural and commercial reasons – camera phones (and mobile phones in general) were adopted earlier and at a faster rate than in North America and other areas of the world. For studies in European countries see the work of experts such as Dr. Barbara Scifo in Italy (2005, 2009; Colombo and Scifo, 2005); Dr. Leslie Haddon in the UK (2005, 2007) of the London School of Economics; and in Finland Dr. Virpi Oksman (2005a, 2005b, 2006) of Tampere University of Technology and Dr. Ilpo Koskinen (2006, 2008) of the University of Helsinki. Researchers were also examining the uses of camera phones in the emerging Asian information societies of Japan and South Korea. One of the best book-length treatments from this time is Dr. Mizuku Ito, Dr. Misa Matsuda and Dr. Daisuke Okabe’s edited work *Personal, Portable, Pedestrian: Mobile Phones*

in Japanese Life (2005). In the introduction Dr. Mizuko Ito of the University of California at Irvine writes that the *keitai*, the nominal term for mobile phone in Japan, has become an organizing and socializing force in outside and routine settings for Japanese people vis-à-vis the more hypermediated indoor spaces of video and computer monitors.

In contrast to the cellular phone of the United States (defined by technical infrastructure), and the mobile phone of the United Kingdom (defined by the untethering of fixed location), the Japanese term keitai (roughly translated, "something you carry with you") references a somewhat different set of dimensions. A keitai is not so much about a new technical capability or freedom of motion but about a snug and intimate technosocial tethering, a personal device supporting communications that are a constant, lightweight, and mundane presence in everyday life. (p. 1, author's emphases)

In their ethnographic study of camera phone use in Japan, Ito and her colleague Dr. Daisuke Okabe of Keio University (2005) find the device's principle use as a networked portable camera, where photos can be 'stored,' 'shared,' and 'saved.' But the camera phone has some more immediate uses than its analog, camera-only predecessor since photos could be stored and then instantly displayed, i.e., "shared," with others in the same location or shared by posting to virtual communities. Most phones also came with cords to connect to computers so photos could be saved in personal archives and printed.

For studies of camera phone use in South Korea see Haddon and Kim, 2007; Hjorth, 2007; and Ok, 2005. Dr. Larissa Hjorth (2007) of RMIT University places Korean camera phone practices in the context of a country where media technology innovation and use is a source of national pride. "By scripting itself as a centre for digital, convergent technologies," she writes, "Korea is rewriting its history through the global currency of ICT production" (p. 228) In her ethnographic study of how a group of youth used camera phones

Hjorth found the content categories of photos taken to be somewhat similar to those reported by Scifo in Italy: "everyday, special occasions/places, friendship/family, self-portraiture, and favourites" (Hjorth, 2007, p. 234). She notes that for many of the study participants the photo taking, posting, ringtones, and wallpaper choices revolved around their involvement in romantic relationships. "For the youth of Korea, where most still live at home before getting married, these third spaces," between home and work or school, she observed, "operate as spaces to connect with other people" (p. 230).

The young adults studied by Hjorth rarely used MMS to send picture messages. Instead they posted photos to a virtual community, "Cyworld's mini-hompy." Hjorth interprets people's preference for using mini-hompy rather than MMS as due to "a broader shift in web 2.0 towards the user's choice of context informing the content and distribution of their images in a social network" (p. 236). In a 2005 study of youth using the mini-hompy community Hjorth and Kim conclude that "virtual connecting was always about the need and desires to be connected at various levels and never about substituting for face-to-face contact" (Hjorth, 2007, p. 230). Although this small study cannot be generalized, it offers another possible reason why MMS use for picture messaging did not quickly take off in many countries, since company's like Nokia believed that one of the most popular uses of MMS would be as a substitute for face-to-face communication (Lillie, 2012).

Some more recent studies have considered how the use of mobile phones as a whole, including imaging functions, is caught up in identity development and self-expression. The studies and edited anthologies by Dr. James Katz of Boston University are well known in this area. Katz and Sugiyama (2006), who surveyed students in the USA and Japan, concluded that, "young people use the mobile phone as a way of expressing their sense of self and perceive others through a 'fashion' lens" (p. 281). James Katz's edited book *Handbook of Mobile Communication Studies* (2008) is one

of the best collections in this field due to the large variety of country studies it includes, each focusing on the specifics of mobile phone use in one national or sub-national context. Another excellent book-length work is *Moving Cultures: Mobile Communication in Everyday Life* (2007) by Dr. Letizia Caronia of the University of Bologna and Dr. Andre Caron of the University of Montreal. One of their studies focused on how teens used mobiles to explore processes of identity making through public performance. Mobile performances, they argue, “work as a social grammar through which people are supposed to define themselves and those around them” (p. 28). In fact, long before the advent of camera phones, personal cameras have served a similar role. Social and personal practices of picture taking and viewing helps people to understand their relation to the world, not just the world itself. As one noted scholar put it, “photography, more than merely representing, has taught us a way of seeing...that...has transformed contemporary self-knowledge” (Lury, 1998, p. 3). Media archeologist Erkki Huhtamo (2004) astutely observed that the mobile phone was certainly not the first mobile media device, being predated by the Walkman and more importantly for this topic, the portable camera. As Ito and Okabe (2005) and other researchers have found, the popularity of camera phones are due mostly to their advances of the standard portable camera, which has been a common technology of families in developed countries for many decades.

Nokia of course was aware of the slow uptake of MMS and conducted its own research to find a solution to this problem. “Apparently, usage has not emerged from merely experimenting with multimedia messages to every day usage, as has happened with SMS,” suggested one Nokia research paper (Pohjola and Kilkki, 2005, p. 1). In these early years, manufacturers and carriers were also trying to fix problems of interoperability for MMS. This continued to be an issue because there was a wide disparity between the technical capabilities of different handsets and different network providers. An MMS sent from a person

using one network carrier might not be properly handled or decoded by a different carrier. Or the receiver’s handset might not be able to download or display some or all of the message. Lacking the ability to quickly fix problems such as handset usability, cellular coverage, or MMS message interoperability, Nokia addressed the lack of user interest in person-to-person picture messaging in 2003/4 by trying to better understand user experiences of MMS and then using this knowledge to design new marketing campaigns for its latest camera phone models. One of Nokia’s studies during this period was aptly titled, “What is wrong with Multimedia Messaging?” The study provided an end-user cost-benefit analysis based on the behaviorist assumption that, “End-users have various needs and wants that they can fulfill using an MMS service” (Pohjola and Kilkki, 2005, p. 1) and offers a conceptual model of how user experiences influence behaviors involved in a person-to-person MMS. The report notes that advertising can demonstrate the ideal user experience, but negative experiences of poor network coverage, high per-message costs, or confusing handset interfaces will unravel any gains made through marketing. Nokia’s subsequent advertising applied this model by demonstrating how people learn about and experience MMS and showing how this experience can fulfill their needs (Lillie, 2012).

M

MOBLOGGING AS MMS INNOVATION

It was around 2005 that the use of MMS to upload content to image-sharing websites began to garner more attention from users, service providers, and cultural critics. In particular, the practice of “moblogging” began to emerge among photography enthusiasts and programmers who realized that MMS was well suited for users to upload photos and videos from handsets to websites, since MMS media is already stored on a server before it is delivered when someone views the message on their phone (Loubser, 2005, p. 4). Moblogging was

pioneered by amateur innovators experimenting with SMS, WAP (the first 2G and 3G standard for connecting to mobile-optimized websites), and eventually MMS to post messages and eventually photos to their modified blogs (Goggin, 2005, p. 5). Dr. Gerard Goggin (2005, 2006, 2008) of the University of Sydney is one of the first researchers to study mobile blogs. He found that these early innovators have various motivations for posting photos to their blogs (2005). Some were happy to develop a new way to share aspects of their daily lives with friends and the public, while others hoped this new web-publishing innovation could offer more socio-political reach. Goggin has single authored or edited several noted titles in this area including *Cell Phone Culture* (2006), *Mobile Media* (2007) and *Global Mobile Media* (2011).

Industry took note of moblog innovation and began to develop online image services to go beyond simple photo archiving to offer, “more playful community activities, involving guessing and mocking games, and the introduction of tagging” (Nightengale, 2007, p. 290). To encourage users to upload images and engage in various web-based services and communities, manufacturers like Nokia started introducing handsets with non-removable image memory to replace early models that featured removable memory cards (Nightengale, p. 291). Goggin recounts how Nokia was the first industry player in Europe to create commercial moblog-like services for their customers, starting in 2005 with the launch of “LifeBlog” (2006, p. 159). Nokia’s Lifeblog was one of the company’s first efforts to encourage user practices that utilize MMS to upload photos to websites. Taking advantage of the way MMS already worked, any picture that had been sent phone-to-phone could be selected by the user for display on her Lifeblog page. In 2007 the company rolled its moblogging offerings into a more comprehensive suite of services dubbed the “Ovi Portal.” Ovi included the Nokia Music Store, Nokia Maps, mobile games, moblogs. Many of these services used MMS for uploading and downloading of content to and from handsets.

But 2007 is better known in the computer world for being the year Apple began selling its touch screen smartphone, the iPhone. Nokia had been an innovator in the smartphone category years earlier with its successful 9000 series. Although the company had the foresight to make all mobile handsets camera phones, it continued to envision smartphones as a niche business-class product. Smartphones meant users did not need MMS to add photos to their blogs, Flickr albums, or Facebook pages. Facebook began allowing photo uploads as early as 2005 and was an early innovator in using mobile web standards and developing mobile apps for emerging mobile operating systems like iOS and Android.

CONCLUSION

Of course eventually there were new killer apps in the mobile phone world to follow up on the success of SMS texting. But it was not traditional wireless carriers and handset manufacturers who were the hardware and software innovators. It was computer industry giants like Apple who championed smartphones, devices that were almost always connected to the internet and therefore allowed users to share camera-phone captured media and socialize via social media web sites that became killer apps of their own. MMS is still used today, especially in areas where smart phones are too expensive for the average user. But the face of photo sharing today is Instagram, Snapchat, Facebook, Flickr, Tumblr, and Twitter. The type of creative visual communication that Nokia envisioned and that studies such as Ito and Okabe (2006) and Scifo (2005) found practiced among some early users of MMS, is now commonly seen as conversations on Facebook through both “News Feeds” and private messaging. And even the goliath Facebook is losing its popularity among younger users who prefer to use apps like Instagram and Snapchat for photo sharing (CITE). Use of MMS in the early and mid 2000s might have even primed some users for how they could

communicate via smart phones with social media apps. Hjorth's finding that South Korean youth preferred posting photos to virtual communities rather than using MMS perhaps anticipated the possibility that sharing media predicated on social peer-group communication would eventually eclipse what Nokia and others hoped MMS would be.

A large portion of today's visual culture is created by industry, and it is important not to downplay the roll that marketing processes of transnational corporations like Nokia play in deciding which technologies are available, how people make meaning through them, and how people use them. Although mobile phone advertisements have rarely been studied, they are integral in introducing new media technologies to users. Two scholars who study the history and cultural implications of marketing, John Harms and Douglas Kellner (2003), argue that advertising has "multi-faceted social functions ranging from short range efforts to induce individuals to buy specific products to more long range functions that attempt to sell consumer capitalism as a way of life." However, as we see in the example of Nokia's heavy marketing of MMS, advertising can only give users suggestions for how to use technology. The use of the camera phone as a discrete, portable, digital camera with easy display of archived pictures as it turns out was the more intuitive and useful feature, following up on decades of amateur photography practices familiar to most people in developed countries. Writing about the cultural significance of amateur photography in the 20th century Susan Sontag observed in 1977 that, "[t]o photograph is to collect the world. It means putting oneself into a certain relation to the world that feels like knowledge – and, therefore, like power" (1977, p. 3-4). But as a cultural practice amateur photography rarely reached into the public sphere – except when appropriated by commercial media – before web-based visual practices starting with homepages and moblogs and now via social media. The so called 'social media revolution' would probably not be what it is today without the industry and

user innovations of camera phones and messaging systems like MMS.

All of this effort toward product development and marketing obviously has some impact, though certainly not total control, over how people use, identify, and make meaning of, and with, new commercial ICTs. As Snowden's study (2007) of SMS showed, texting itself was not some completely unexpected use of the mobile phone. Policy makers, engineers, and many companies such as Nokia worked very hard to bring SMS technology to the market. What was unexpected was how texting use boomed due to its massive uptake by teenagers and young adults as a form of everyday peer-group socialization. But no amount of advertising was able to entice people to use MMS picture messaging at the same frequency as they did with SMS. Thus the cultural life of a media technology traverses a complex web of user identities and appropriations, social meanings, institutional (often national) discourses, and industry design rooms.

FUTURE RESEARCH DIRECTIONS

Noted cultural theorist W.J.T. Mitchell (1994) describes a pivotal "pictorial turn" of contemporary culture in the 20th century: "a postlinguistic, post-semiotic rediscovery of the picture as a complex interplay between visibility, apparatus, institutions, discourse, bodies, and figurality" (p. 16). Certainly the camera phone seems to fit perfectly in an era of proliferating visual media, and in particular as part of the personal-to-public digital media revolution that started off with personal homepages in the early 1990s. However, it is important to note that before the camera phone, the mobile phone was still mostly an interpersonal communication device. And that is how MMS was intended to be used by Nokia and others. Today that is still what the standard is still largely used for, especially by those who do not have smartphones, which can directly use web-based services like Facebook and Twitter. And while camera phones might just seem

like a logical, intuitive step in the incessant march of a postmodern, visual-dominated culture, it is vital to remember that it is people as individuals, communities, corporations (and other groupings) who create that culture and its technologies; and therefore to study the cultural aspects of media technologies we must analyze as many of those groups (and their contexts) as possible.

KEY TERMS AND DEFINITIONS

Camera Phone: Any mobile phone with a built-in camera.

Cell Phone: A popular term used in many countries for mobile phones, arising out of the longer-term ‘cellular phone,’ indicating the devices’ uses of cellular radio systems for voice communication.

Cultural Studies: A mostly academic, scholarly movement in the humanities that argues for multi-disciplinary and intra-disciplinary approaches to studying cultural groups, with particular focus often on media use.

Mobile Phone Culture: A term used to describe how individuals and groups use mobile technology in their everyday lives.

Multimedia Messaging Service (MMS): A mobile phone service that allows the sending and receiving of messages combining text, photos, and short video clips.

New Media Studies: The study of how and why people use new media technologies, including a range of approaches in the social science and humanities.

Technological Innovation: A variety of scholars from different disciplinary backgrounds have studied how people and companies create new uses for new or existing technologies, and how these new innovations diffuse within populations.

Viterbi Decoder in Hardware

M

Mário Pereira Véstias

Instituto Politécnico de Lisboa, Portugal

INTRODUCTION

Trellis decoding is used to recover encoded information that was corrupted during transmission over a noisy channel. The Viterbi algorithm is the most well known trellis-based maximum likelihood decoding algorithm. The Viterbi algorithm is executed by a Viterbi decoder. Different hardware solutions may be considered to implement a Viterbi decoder with different design requirements in terms of area, performance, power consumption, among others. The most appropriate solution depends on the metric requirements of the application as well as on the target technology.

Properties of the Viterbi algorithm are used to simplify and improve the architecture of the Viterbi decoder. In particular, statistical properties of the Viterbi algorithm are used to design parallel Viterbi decoders with very high data decoding rates.

The article focuses on the implementation of a Viterbi decoder in hardware, including optimizations to improve the area and performance.

BACKGROUND

Generically, a communication system includes a channel encoder at the transmitter and a channel decoder at the receiver. Encoding the bit stream to be transmitted reduces the energy per data bit needed to achieve the same bit error rate (BER) over a noisy channel compared to a non-coded transmission. A better channel code needs lower energy to obtain a particular BER.

Convolutional Encoder

Two major classes of binary codes are block codes and convolution codes. In this article we are only concerned with convolution codes (P. Elias, 1955). Convolution codes operate over a continuous bit stream. A convolutional encoder is used to generate the encoded bitstream. A typical implementation consists on a shift register and a set of modulo-2 addition. The content of the shift register defines the state of the encoder (s bits), from which we obtain a finite state machine with $m = 2^s$ states. Figure 1 shows an example of a

Figure 1. Convolution encoder with rate 1/2

DOI: 10.4018/978-1-5225-2255-3.ch549

convolution encoder with rate 1/2 (rate 1/c generates c bits for each input bit) and its state machine.

An alternative way to represent the behavior of the encoder was proposed by Forney (G. D. Forney, Jr., 1967) designated *trellis representation*. A trellis is one of the most convenient ways to visualize the behavior of the decoding algorithms (see Figure 2).

Each node in the trellis represents a state of the FSM. After m time steps, the trellis is full and the branch pattern repeats indefinitely.

Most work on trellis decoding was dedicated to the codes with a rate of 1/2. This type of codes will provide the simplest trellis decoding since there are only two nodes leaving and entering a state.

Viterbi Algorithm

The Viterbi algorithm (VA) was proposed in 1967 by Andrew Viterbi (Viterbi, 1967). The algorithm decodes convolutional codes with an optimum non-sequential algorithm. Contrary to previous algorithmic solutions whose complexity increases exponentially with the length of the encoded sequence, the computational complexity of the Viterbi algorithm increases linearly with the length of the bit stream. The algorithm has three main steps: (1) branch metric calculation; (2) trellis calculation; and (3) traceback decoding.

The branch metric, bm , calculation determines the squared Euclidian distance, between the re-

ceived symbol, r_k , and the expected symbol associated with a branch of the trellis diagram, c_k , that is, r_k . At every time step, $|r_k - c_k|^2$ branch metrics are calculated since each state has two input branches.

The linear computation complexity of the VA is achieved by discarding unlikely branches in the trellis diagram using the Principle of Optimality (Bellman and Dreyfus, 1962). According to this, whenever two paths of the trellis diagram merge into the same state only the path with the best metric (most likely) must be kept. This path is designated *survivor path*. At each time step, this operation is applied to all paths and m survivor paths are obtained at each time step. Formally, a state metric, $sm(state)$ (see Figure 3), is updated as follows:

$$2 \times m$$

At each time step, the trellis calculation step obtains m decision symbols, one for each surviving branch. These symbols must be stored to help recover the symbols responsible for specific transitions during the traceback decoding step.

The trellis computation stops after a predetermined number of steps or after the decoding of the complete stream. From the m survivor paths, the final step (traceback decoding) starts in the state with the best metric and tracebacks through the

Figure 2. Trellis diagram of the encoder in Figure 1

Figure 3. State metric update

path identified by the decision bits until reaching the first state and, consequently, obtain the most likely sequence of symbols.

The higher the number of steps before starting the traceback process, the higher the latency and the memory requirements. To reduce the latency and/or memory requirements the trellis process can be stopped after a pre-defined number of steps by, for example, considering extra bits that terminate the trellis in a defined state. The disadvantage of the method is the overhead associated with the introduction of bits with no information. Fortunately, the VA has one property that allows us to stop the trellis process in the middle of the decoding process and still recover the trellis path. Considering the m survivor paths at a step in the trellis diagram, when traced back, these paths merge into a single path (see Figure 4).

Formal estimations of L can be found in the literature (Anderson and Balachandran, 1989). However, in practice, the required value for L is found by simulation.

VITERBI DECODER IN HARDWARE

The Viterbi decoder implements the Viterbi algorithm with three functional units, one for each of the three steps of the VA (see Figure 5).

The branch metric unit (BMU) calculates the Euclidian distances associated with each branch for each input symbol. The Viterbi algorithm considers, by definition, that the received sequence is “hard”, that is, the decoded bits are either 0 or 1. Instead of hard decision, soft decision can be considered, where soft bits (several bits) represent real numbers. In practice, at least three bits are used to represent the expected and received symbols.

The branch metrics are then accumulated with the state metrics and the survivor paths are chosen. This is implemented with an add-compare-select unit (ACSU), which adds the metrics, compares the metrics entering a state and selects the best metric. The decisions, d , are stored in a memory and used by the traceback unit (TBU) to recover the symbols associated with the survivor path.

Figure 4. Traceback of survivor paths merging into a single path

Figure 5. Viterbi decoder

In the following, code rates of $1/c$ are considered. This assumption not only simplifies the trellis decoding, since there are only two nodes leaving and entering a state, but also simplifies the implementation of the branch metric and the add-compare-select units.

Branch Metric Unit

The Euclidian distance between a received symbol, r , and the expected symbol associated with a branch of the trellis diagram, c , is $sm(S_a^{t+1}) = \min(S_b^t + bm(S_b^t, S_a^{t+1}), S_c^t + bm(S_c^t, S_a^{t+1}))$ applied to all dimensions, d . Formally,

$$|r - c|^2$$

In the equation, both squares, $b_m(r - c) = \sum_{n=0}^{d-1} (r_i^2 - 2r_i c_i + c_i^2)$ and r_i^2 contrib-

ute equally to the equation and thus can be neglected. So, the equation simplifies to:

$$c_i^2$$

Considering noiseless symbols 0 and 1 of c represented by the symmetrical values -1 and +1, the branch metric reduces to add/subtraction of the received values

$$b_m(r - c) = -\sum_{n=0}^{d-1} (r_i c_i)$$

Therefore, only additions need to be implemented to calculate the branch metrics (see example in Figure 6 for $1/3$ code rate).

The unit can be reduced to half since $b_m(r - c) = -\sum_{n=0}^{d-1} \pm r_i$. For example, $b_m = -\overline{b_m}$. Both branch and complemented branch are gener-

Figure 6. Simplified branch metric implementation

assigning multiple add-compare-select operations to a single ACS unit (*folding factor*) (Shung, et al., 1993 – part I), (Shung, et al., 1993, – part II). The time-multiplexed implementation reduces the number of ACS units, but there is an increased design complexity relative to the controller and an increase in the number of registers. Also, the critical path increases due to extra multiplexers to route data to a single unit which reduces the expected linear increase operating frequency considering the folding factor.

When the encoded data is received in a continuous stream of bits, the path metric which is the accumulated value of the branch metrics, may overflow. To avoid overflow, the path metrics must be normalized. A very efficient technique that avoids overflow is the modulo normalization technique (Shung et al., 1992) that automatically normalizes the path metric. In modular arithmetic the metric, m_j , is replaced by the normalized metric $\hat{m}_j = 2^s$, where C is the maximum value represented by the number of bits used for defining the path metric. The differences in the survivor metrics remain unchanged using modular arithmetic provided that $\hat{m}_j = (m_j + \frac{C}{2})(\text{mod } C) - \frac{C}{2}$, where diff is the bound of the difference between survivor metrics.

Formally, the required number of bits for the state metric is given by:

$$\text{diff} \leq \frac{C}{2}$$

$$\text{W h e r e } S_{\text{bits}} = \lceil \log_2(2 \times \Delta_{\text{max}}) \rceil ,$$

$\Delta_{\text{max}} = \lambda_{\text{max}} \log_2 m = \text{maximum branch metric}$ and m is the number of states. For example, for 64 states, and code rate of 1/3, $\lambda_{\text{max}} = 18$. So, $S_{\text{bits}} = 8$. This normalization is implemented in hardware using a 2's complement adder.

Another simplification rule following the metric calculation using modular arithmetic is the modified compare (Shung et al., 1992). The modified comparison rule applied to two normalized metrics with p bits λ_{max} and $\hat{m}_x = (mx_{p-1} + mx_{p-2} + \dots + mx_0)$ is given by:

$$\hat{m}_y = (my_{p-1} + my_{p-2} + \dots + my_0)$$

where $y(\cdot)$ denotes the unsigned comparison. In general, this comparator is smaller and faster than using a subtractor to implement comparison.

A few optimizations techniques have also been proposed to improve the performance of the

Figure 8. Parallel ACS unit implementation

ACS unit. For example, an ACS parallelization technique was proposed in (Véstias and Sarmiento, 2010) to reduce the critical path of the unit. The critical path of the ACS unit includes one adder, one comparator and one multiplexer. To reduce this critical path, the addition in the ACS unit is done in parallel with the comparison (see Figure 8).

The comparator determines the addition output with the lowest value according to the following equation

$$mx_{p-1} \oplus my_{p-1} \oplus y(mx_{p-2} + \dots + mx_0, my_{p-2} + \dots + my_0)$$

$$\text{Since } d_s^t = (m_{y \rightarrow x}^{t-1} - b_{m_z \rightarrow x}) - (m_{z \rightarrow x}^{t-1} - b_{m_z \rightarrow x})$$

$$b_{m_z \rightarrow x} = -\overline{b_{m_z \rightarrow x}}$$

Results indicate improvements of around 50% in the delay considering a *Field Programmable Gate Array* (FPGA) implementation.

Trace-Back Unit

The trace-back unit receives the accumulated metric values of all states, finds the state with the lowest value and returns the path ending in this state, that is, the sequence of bits that best matches the received sequence.

To find the state with the lowest metric all m metrics are compared. Several architectures with different area/performance tradeoffs can be considered to determine the maximum of a set of values. A fast approach is to use a tree of comparators having $\log_2 m$ levels, that is, $d_s^t = (m_{y \rightarrow x}^{t-1} - m_{z \rightarrow x}^{t-1} + 2 \times b_{m_z \rightarrow x})$ comparators at

the first level, $\frac{m}{2}$ at the second, and so on (or $\frac{m}{4}$ shared comparators). After $\log_2 m$ cycles, the state with the lowest metric is identified. The solution is fast but expensive in terms of hardware resources. An approach with small area is to con-

sider a recursive process where at each iteration the highest value found so far is compared to a next value. This sequential solution takes m cycles to complete, increasing considerably the latency and may become the bottleneck if the ACS step takes less than m cycles. Usually, an efficient solution is to consider a tree of iterative comparators (Véstias et al., 2012).

Given the state with the highest metric, the TB unit starts from this state and determines serially the values of the decoded bits ($b_0, b_1, b_2, b_3, \dots, b_{\text{TBL}-1}$), where TBL is the trace back length or the number of time steps in the trellis diagram before traceback. The circuit determines the backward path based on the decision bits found during the calculation of the paths. From a state and a decision bit the block finds the previous state. The process repeats iteratively until all decision bits are found. Two properties of the trellis diagram are used to find the correct path. One of the properties is that there are transitions

to states from 0 to $\frac{m}{2}$ if the input bit is 0 and to

states $\frac{m}{2} - 1$ to $\frac{m}{2}$ if the input bit is 1. This is easy to check since the most significant bit of the state is the input bit. The other useful property states that the preceding states are obtained by shifting the bits identifying the state one bit to the left and introducing 1 or 0. For example, the preceding states of 17 (010001) and 49 (110001) are 34 (100 010) and 35 (100 011). The correct previous state depends on the decision bit stored during the trellis decoding. The property results from the fact that the next state is obtained by shifting the state one bit to the right. Both properties are used to implement the TB unit (see Figure 9).

The state with the best metric is initially stored in the state register. Then the content of the state register evolves iteratively according to the stated property to find the previous state. The output block $m - 1$ implements the first property to determine the decoded bit.

Figure 9. Implementation of the TB unit

VITERBI DECODER PARALLELIZATION

The parallel VD approaches improve the decoding throughput by increasing the number of state updates at a single time step. A way to achieve this is to apply a lookahead technique of two or more levels (Fettweis, 1989). The look-ahead technique is a parallelization technique proposed in (Black & Meng, 2002). In a single cycle the technique

updates the state metrics of n consecutive steps and thus ideally increases the throughput n times, compared to a direct implementation. However, there is an area penalty proportional to n . To see how the technique works, let's consider a trellis diagram with states with two inputs and two outputs (radix-2) and collapse two steps into a single one producing a radix-4 trellis diagram (four branches entering and leaving each state) (see Figure 10).

Figure 10. A radix-2 trellis diagram transformed into a radix-4 trellis

We could think about higher radices. However, as concluded in (Black & Meng, 1992), radix-4 solutions are more area efficient than higher radices. Also, the critical path increases due to the extra operations of the ACS unit and the feedback interconnections. In (Black & Meng, 1992), a full-custom implementation of both radix-2 and radix-4 architectures have shown speed-ups of 1.7, lower than the theoretical 2 times speed-up.

Unbounded throughput using parallelization can be obtained with the minimized method (Fettweis & Meyr, 1991) and the sliding-block decoder (Black & Meng, 1997)). Following these techniques, parallel implementations of the VD can be implemented by decomposing the input data into $> \frac{m}{2}$ blocks which can be processed in parallel using k conventional Viterbi decoders. The complexity of the circuit increases linearly with the throughput. However, each block processing requires the initial state metrics to be known and this is only available after the previous block has finished processing. Three techniques have been proposed as a solution to this problem: state initialization (Dunn, 1978), interleaving (Lin & Messerschmitt, 1989) and sliding block (Tzu & Dunham, 1981). The state initialization technique forces the encoder to a known state at the start of each block. This adds complexity to the decoder since it needs block synchronization. The interleaving technique processes independently encoded sequences. However, this approach cannot be used when intersymbol interference is present. The sliding block decoder technique processes independent overlapping blocks simultaneously.

To acquire the initial states, two sync blocks are used at the beginning and at the end of the block. The method is based on two main observations. One is that the survivor paths from all possible starting states merge with high probability L iterations back into the trellis. The parameter is the survivor path length (SPL) and is typically $k \times M$ (Clark & Cain, 1981). The other is that when starting with unknown initial state metrics, the state metrics after K trellis iterations are independent of the initial metrics. The parameter is the synchronization length (SL) and is also typically $5 \times s = 5 \times \log_2 m$ (Viterbi & Omura, 1979).

Based on this characteristics, a state at time n can be decoded using only information from the interval $5 \times \log_2 m$ to $n - K$. Typically, $K = L$ is considered. The sliding block VD (SBVD) method applies the Viterbi algorithm to the interval $[n - M/2 - L, n + M/2 + L]$ to decode the interval $[n - M/2, n + M/2]$. To guarantee correct initial and final states, the method considers an initial synchronization block (SL) and a final trace-back block (SPL) without decoding for each parallel VD (see the behavior of each VD for the SBVD in Figure 11).

With this technique, we can use independent parallel VD to increase the decoding rate (see Figure 12).

The relative area efficiency is $n - L$. As M increases the method approaches the ideal efficiency of 1. However, the bigger the value of M , the bigger the latency and more storing resources are needed to save intermediate states. The decoding rate, DR, of an SBVD is:

Figure 11. Sliding block method for Viterbi decoder

Figure 12. Sliding block method for Viterbi decoder

$$\frac{M}{M + 2L}$$

where nVD is the number of parallel VD and $drVD$ is the decoding rate of a single VD. The bit error rate of the decoding process of the VD depends on the length of the initial synchronization step, the length of the final trace-back length and of the trace-back decode length. All these parameters are usually found through system simulation.

FUTURE RESEARCH DIRECTIONS

Viterbi decoding implementations exist with different implementation tradeoffs including area, performance and power consumption. Parallel techniques allow any decoding rate just by increasing the number of parallel Viterbi decoders and thus an increase in the area and power consumption.

One of the characteristics of the Viterbi decoder is that of being the most resource-consuming compared to other decoding algorithms, but theoretically it does maximum likelihood decoding. However, there are some impediments to yield the ideal maximum likelihood due to several factors, including quantization of the input stream and finite trace back length.

A major challenge in the future of the Viterbi decoder is how to achieve high throughput with low power consumption. This is very important for portable devices.

CONCLUSION

The article describes the backgrounds of the Viterbi algorithm as a way to design a Viterbi decoder. The typical architecture of the Viterbi decoder is explained and implementations of each block of this architecture are provided, including optimizations to get faster or smaller implementations. Parallel solutions are also discussed which permits the design of high throughput Viterbi decoders.

The Viterbi algorithm was proposed in 1967 and since then many Viterbi decoder architectures were proposed. Different design requirements are appearing every day in different technologies, e.g., handheld devices, making the research about Viterbi decoder an actual topic of research.

KEY TERMS AND DEFINITIONS

Add-Compare-Select Unit (ACSU): A unit that accumulates the branch metrics of each branch along the trellis diagram.

Branch Metric Unit (BMU): A unit to calculate the Euclidian distances associated with each branch of the Trellis diagram for each input symbol.

Convolutional Codes: A type of error correcting code used in telecommunications.

Convolutional Encoder: A module used to generate convolutional codes.

Trace-Back Unit (TBU): A unit of the VD that finds the state with the lowest value and returns the path ending in this state.

Trellis Diagram: A type of graph where nodes represent states and each node is connected to at least one previous node (state) and one next node (state).

Viterbi Algorithm: An algorithm to decode convolutional codes with an optimum non-sequential algorithm. The computational complexity of the Viterbi algorithm increases linearly with the length of the bit stream. The algorithm has three main steps: branch metric calculation; trellis calculation; and traceback decoding.

Viterbi Decoder (VD): An implementation of the Viterbi algorithm consisting of three main functional units, one for each of the three steps of the Viterbi algorithm.

Wireless Implant Communications Using the Human Body

INTRODUCTION

Advancements in medical diagnostics and bio-sensing technology opened up a great venue for research in electronic medical implant. To improve accuracy and timeliness of diagnosis, electronic devices could be implanted inside human body to provide various real-time diagnostics information. However, effective technique for implant communication is still an open problem. Early efforts based on radio wave propagation are standardised as the Medical Implant Communication Services (MICS) for 402–405 MHz frequency range which was later adopted as Medical Devices Radio Communications Services (MedRadio) for 401–406 MHz frequency range (Hanna, 2009).

Currently, the radio-frequency (RF) implant wireless communication is enabled by utilizing small antennas that radiate radio waves inside the human body. As a bid to find alternative wireless implant communication mechanisms within the Wireless Body Area Network (WBAN), in this work, the authors explored two complementary techniques. The first uses galvanically coupled Intra-body communication (IBC) for implant-to-surface communication. IBC is a relatively new technique that uses the human body as a channel with communication frequencies not exceeding several MHz. The second technique uses the human body itself as an antenna by feeding an RF current into the tissues.

This chapter first examines a new analytical electromagnetic model that uses galvanically coupled IBC where the implant transmitter differentially injects current into the tissue via its anode and cathode electrodes. A wearable receiver on the surface of the skin samples the resulting potential difference using its two electrodes. Frequencies ranging from hundreds of kHz up to a few MHz are considered under quasi-static assumptions. The model is unified in the sense that it is based on multilayered ellipsoidal geometry that can be applied to any part of the body (i.e., head, torso, limbs etc.). It also effectively describes influences of tissue properties and geometry of the body part. The security and low power consumption of IBC are also apparent in this model. The path loss characterisation of IBC implants shows lower values compared to their MICS counterparts.

In addition, the chapter also elaborates on the scenario when the RF current is fed by a tiny toroidal inductor that is implanted and clamped around the tissues in the ankle. The frequency range of 1–70 MHz is considered, which includes the resonance frequency of the human body. Theoretical results show that the system exhibit broadband characteristics with a maximum gain of - 25 dB between 20 to 40 MHz, assuming an isotropic radiation from human body. However, for the case of the small toroidal inductors considered, the radiation resistance of the system is very small, which increases the power consumption.

BACKGROUND: IMPLANT COMMUNICATION IN THE WBAN ARCHITECTURE

To improve accuracy and timeliness of diagnosis, and hence improve quality of life, sophisticated actuators and biosensors are emerging for various diagnostic applications; for example, glucose sensors for continuous diabetes monitoring (Heo et al., 2013). In broad terms, implant communication technique explored in literature use radio wave propagation, magnetic induction and volume conduction (Poon, 2010), (Bjorninen et al., 2012), (Yang, 2006).

For implant communication it is important that the transmitter consumes small power to conserve battery life. The implant should also be miniaturized for a minimal invasive embedding. Besides, due to sensitive nature of medical data, security is a paramount requirement of implant communication. To achieve security either the signal needs to be encrypted at the transmitter or be confined to within the body detectable by as far as an on-body receiver. In the case of MedRadio based implant, the signal is radiated outside the human body; hence, requires all security features be implemented right at the transmitter which increases the transmitter complexity. Hence, the transmitter consumes large power and is difficult to miniaturise.

Implant communication scenario can be divided as implant-to-implant, implant-to-surface, and human body to external environment. The authors explored the use of galvanically coupled IBC for implant-to-implant and implant-to-surface scenario; and the use of the human body itself as an antenna for a possible scenario of communicating implant inside human body to external environment.

The general architecture of body area sensor networks, as shown in Figure 1, is that a link node wearable on the surface talks to and listens from the implanted and other surface mounted devices. It then combines and relays the signal to devices external to the body – mainly a monitoring or

controlling device away from the body. Another likely scenario is the possibility of two implants talking to each other; for example, a glucose sensor and an insulin pump. To reduce complexity and power consumption it is better to implement advanced security features at the link node rather than each individual implanted or on-body device. To avoid eavesdropping attempts to listen or talk to sensors in and on the body by any transceiver external to the body, the signal needs to be confined to within the body. For frequencies ranging from a few hundreds of kHz to tens of MHz, the human body hardly radiates radio waves. Thus, this band is suitable for body confined (intra-body) transmissions – implant-to-implant, implant-to-surface and surface-to-surface communications.

To communicate the signal to outside the body wirelessly, radio wave propagation of RF signals is required. Such is the case for the link node or possibly an individual implant desired to directly communicate with the outside environment. For this scenario, the authors explored using the human body as an antenna. Specifically, frequency ranging from 10 – 110 MHz was considered. If the human body is excited by an RF current in this frequency range, the human body radiates electromagnetic signals. Furthermore, the human body resonance frequency is found to be between 30 – 70 MHz which falls within the frequency of interest. Transmission power levels within human tissues considered in this chapter are in accordance with the safety recommendations of Specific Absorption Rate (SAR) levels by the International Commission on Non-Ionizing Radiation Protection (ICNIRP) (ICNIRP, 1994).

THE HUMAN BODY AS A CHANNEL FOR IMPLANT COMMUNICATIONS

The HBC uses an electric field communication (EFC) where the human body is effectively a volume conductor. It exploits the lossy dielectric nature of the conductive tissue layers to induce a current, and hence a potential distribution, as a

result of the electric field caused by the current injected by the transmitter electrode(s). Such a low frequency signal is expected to penetrate deeper into the tissue layers, thus requiring less power be detected by a receiver on the surface of skin. Moreover, due to a non-conducting free space outside the skin surface, the signal is confined to within the human body (i.e., inherently secure).

GALVANICALLY COUPLED IBC MODEL FOR IMPLANT COMMUNICATION

In literature, several modeling techniques have been used to model the human body as a channel. Some of these techniques include the two-terminal circuit model (Besio, 2006), (Hachisuka, 2006), four-terminal circuit model (Hachisuka, 2006), (Kibret et al., 2014), finite element approach (Wegmueller et al., 2006), (Amparo et al., 2014), surface electromagnetic propagation models (Ruiz, 2006), (Bae, 2012), nearfield electromagnetic models (Bae, 2012) and quasi-static electromagnetic models (Pun, 2011). Each model shows various

useful aspects of intra-body communication. However, the electromagnetic models used are based on simple geometries which limit their use to only specific regions of the body. On the other hand, circuit models are generally short-sighted in the sense that the relationship between channel variations and circuit components is not obvious in the transfer functions, albeit well characterized channels in fixed settings.

The analytical electromagnetic model presented on this chapter is motivated by geometries robust enough to capture tissue layer effects in a scalable way that can be applied to any part of the body and yet simple enough to guarantee analytical solutions. Based on this geometry, a mathematical model of the channel is derived to characterise the received signal as a function of the size of the transmitter, tissue layers of the body part, transmitter location, receiver location and electrode spacing.

Most body parts can be approximated by a variation of the ellipsoidal geometry as shown in Figure 2. For example, the human head can be modeled using an ellipsoid close to spherical symmetry. The torso can be modeled by a pro-

Figure 1. Implant communication the WBAN architecture

Figure 2. Ellipsoidal approximation of the human arm

late or oblate spheroid versions of the ellipsoidal geometry. Limbs can be modeled by an ellipsoid where a dominating semi-axis represents the limb length whereas the other two axes represent the larger and the shorter radii of the limb. When one of the semi-axes is large and the other two are comparable, the geometry resembles a cylinder which is often used in existing electromagnetic models e.g. (Pun et al., 2011), (Amparo et al., 2014).

Hence, an analytical model based on multilayered ellipsoidal representation of tissue layers can represent the various body parts by defining the semi-axes lengths. The ellipsoidal shells in the layers represent each tissue layer with varying thickness and complex permittivity.

VOLUME CONDUCTION THEORY FOR IMPLANT COMMUNICATION

Volume conduction can be defined as a transmission technique for electric field inside the volume of a lossy dielectric where an electric field is induced by a primary current source; and this field propagates to the receiver by means of an induction current induced in the conductive medium (Tenke

et al., 2012). An implant transmitter coupled galvanically can be envisaged as the primary current source inside any one of the layers of body tissue. The total current inside the volume (i.e., primary and induction currents added) creates an electric potential distribution inside and on the surface of the volume (Rutkove, 2007). The receiver could be either another implant or on-body device where its two electrodes are used to sample the potential difference between the two points of the body the electrodes are connected to. The transmission frequencies we consider are smaller than the high frequency band of the spectrum. From the conductivity and permittivity profiles of human body tissues at these small frequencies, electromagnetic signals in the body can be assumed to be quasi-static (Pun et al., 2011), (Plonsey et al., 1967). In quasi-static assumptions, the variations of electric and magnetic fields, denoted as $\mathbf{E}$ and $\mathbf{B}$ respectively, with time are negligible. Hence, the set of Maxwell's equation describing the fields inside the human body can be modified as given in (1).

$$\nabla \times \mathbf{E} = 0, \quad \nabla \times \mathbf{B} = \mu \mathbf{J}, \quad \nabla \cdot \mathbf{E} = 0, \quad \text{and} \quad \nabla \cdot \mathbf{B} = 0 \quad (1)$$

where μ is permeability of free space and $\mathbf{J}$ is the net current density inside the volume. Here, the electric field $\mathbf{E}$ is given as

$$\mathbf{E} = -\nabla V, \quad (2)$$

where V is the electric potential distribution. The current inside the volume is due to the conduction source current density $J^s(r) = Md(r - r_0)$ $J^s(r) = \mathfrak{M}\delta(r - r_0)$ and the induced current density $J^i(r) = \sigma(r)\mathbf{E}(r)$ where $\sigma(r)$ is the conductivity of the tissue layer at point r in space, $\mathfrak{M}$ is the electric dipole moment and r_0 is the point in space that is mid-way between the transmitter electrodes. Thus, the net current density $J(r)$ is given as

$$J(r) = \mathfrak{M}\delta(r - r_0) + \sigma(r)\mathbf{E}(r). \quad (3)$$

No current flows out of the human body due to the non-conducting medium (air) outside the body; hence, $J(r)$ is a divergent free current density (i.e., $\nabla \cdot J(r) = 0$). Taking the divergence of (3) and replacing (2) into (3), we can see that

$$\nabla \cdot \sigma(r) \nabla V(r) = \nabla \cdot \mathfrak{M} \delta(r - r_0). \quad (4)$$

Equation (4) is the governing equation for the electric potential which takes different forms for the parts of the volume; i.e., it takes the form of a Poisson's equation in the region (layer) that contains the source and takes the form of a Laplace's equation in the layers that do not contain the source.

POTENTIAL DISTRIBUTION: AN EXAMPLE SCENARIO

In this section, the solution for the potential V in Equation (4) is presented for an example scenario shown in Figure 3. The scenario considered is the case where a transmitter is implanted inside the muscle tissue of the human arm and the receiver is placed on the surface of the skin. In this case four tissue layers are considered; i.e., bone, muscle, fat and skin. The tissue layers are represented by multi-layered confocal ellipsoidal shells.

The appropriate coordinate system to solve for the potential is the Ellipsoidal coordinate system. The solution of (4) in Ellipsoidal coordinate systems can be simplified by using special functions called Lamé's functions of the first and second kind (Dechambre, 2000). The general form of the potential distribution inside the i^{th} layer is given by

$$V_i(\lambda_1, \lambda_2, \lambda_3) = \sum_{n=0}^{\infty} \sum_{p=1}^{2n+1} A_{(n,p)}^i \mathbb{E}_n^p(\lambda_1, \lambda_2, \lambda_3) + \sum_{n=0}^{\infty} \sum_{p=1}^{2n+1} B_{(n,p)}^i \mathbb{F}_n^p(\lambda_1, \lambda_2, \lambda_3), \alpha_1^i \leq \lambda_1 \leq \alpha_1^{i-1}, \quad (5)$$

where λ_1, λ_2 , and λ_3 are the ellipsoidal coordinate system, $\mathbb{E}_n^p$ and $\mathbb{F}_n^p$ are the Lamé's function of first and second kind, respectively, with degree p and order n . $A_{(n,p)}^i$ and $B_{(n,p)}^i$ are the coefficients corresponding to the i^{th} tissue layer and α_1^i is the dominating semi-axis length of the i^{th} tissue layer. Equation (5) is the general solution and specific solution for every scenario is provided by thoroughly specifying the coefficients $A_{(n,p)}^i$ and $B_{(n,p)}^i$ by applying Dirichlet and Numan boundary conditions at each layer.

Figure 3. Implant communication scenario where the transmitter is implanted inside the muscle tissue of the human arm and the receiver is mounted on the surface of the skin

PATH LOSS AND POTENTIAL DISTRIBUTION

To calculate the potential distribution and hence the path loss human arm model given in Figure 3 and Equation (5) are used. An arm of smallest semi-axis 43.5 mm is considered with tissue thicknesses of skin = 1.5 mm, fat = 8.5 mm, muscle = 27.5 mm, bone = 6 mm.

Consider the transmitter injecting an r.m.s. current of 1 mA with its electrodes spaced by 5 mm located along the major semi-axis of the arm at 6.9 mm into the muscle tissue from the muscle-bone interface. The maximum electric potential developed along the axis of the dipole as a function of radial distance from the center is shown in Figure 4. The received potential inside the body decreases at a slower rate inside the body and decreases at a faster rate once the signal leaves

Figure 4. Potential distribution with distance at different frequencies

Figure 5. Path loss as function of distance at different frequencies

Figure 6. Transmitted power as a function of frequency for different skin conductivity

the body. This can also be seen in the path loss which increases at a large slope outside the skin (at 0.0435m from the center) as shown in Figure 5. The path loss at the surface of the skin is around 35 dB which is a lot smaller than the path loss reported for MICS based implants. The impedance of the tissue layer affects the amount of power transmitted. From Figure 6 the transmit power decreases with frequency which due to decreasing impedance with frequency. For a 1 mA r.m.s., the transmitted power is around -32 to -35 dBm; hence, the received power is around -67 dBm to -70 dBm. The received power is thus a lot larger than the average receiver sensitivity of -92.5 dBm required by IEEE 802.15.6 standard. The level of signals considered here are well within the ISNIRP guidelines.

THE HUMAN BODY ANTENNA: IN TRANSMISSION MODE

A remarkable historical attempt to use the human body as an antenna goes back to the 1970s, in a research undertaken by the US army, in an effort to design camouflaged and wearable radio transmitters that use the human body as antenna

(Ikraht et al., 1973). The objective was to replace the traditional infantry whip antennas, which were not suitable to be used in a jungle environment - being physical obstacles to the radio operator. The human body can be completely characterized as a transmitting or receiving antenna from the induced currents in the body. The problem of computing the induced currents can be simplified by considering a typical scenario of a vertically polarized plane wave illuminating a human subject standing on a highly conductive ground. For this specific case, it was assumed that the axial current induced by the vertically polarized electric field is dominant. Other characteristics of the human body as a receiving or transmitting antenna, such as the antenna impedance, radiation efficiency and reflection coefficient, can be derived from the expressions of the axial current.

This problem of characterising the human body as a transmitting antenna is addressed by the authors in their previous work (Kibret et al., 2015) where the human body is effectively characterised as a cylindrical monopole antenna; experimentally confirmed results show that, for a human subject of height 1.76 m and weight 73 kg, it was found that the human body behaves like a monopole antenna with resonance frequency of 40-60 MHz

when fed on the foot depending on the posture of the body. Thus, a transmitter inside the ankle inducing an axial current in the human can act as a feed to the human body antenna.

THE AXIAL CURRENT DENSITY IN THE ANKLE

Since the cross-section of the ankle consists of different tissues, the axial current density is not uniformly distributed.

The tissues have different dielectric properties; therefore, they interact differently to the axial RF electric field passing through them. Accordingly, the authors developed a model for the cross-section of the ankle based on a realistic anatomical atlas of the human body (Netter, 2014) with various tissues assigned specific colours as shown in Figure 7. The 4-Cole-Cole dispersions model was used to represent the dielectric properties of these tissues.

For the frequency range of interest, it was assumed that the axial electric field in the cross-section of the ankle is uniform. The total induced

Figure 7. The cross-section of ankle joint with tissues assigned different colours. 1-muscle, 2-fat, 3-connective tissue, 4-cancellous bone, 5-skin, 6-blood vessel, 7-tendon, 8-nerve, 9-blood, 10-cortical bone

Figure 8. The magnitude of axial current density in the cross-section of the ankle joint with area of 0.0154m^2 for an incident electric field $E_0 = 1\text{ V/m r.m.s.}$

axial current I_z in the ankle, which includes both the conduction and displacement current in the cross-section of the ankle of area S , can be calculated from the axial current density distribution in the ankle J_z as

$$I_z = \int_S J_z ds = E_z \int_S \sigma_s^* ds \quad (6)$$

where E_z is the axial electric field that is taken to be uniform and σ_s^* is the complex conductivity of 'points' in the cross-section. Considering the cross-section of the ankle represented by the grayscale image, the expression in (6) can be approximated as given in (7)

$$I_z \simeq 2E_z \sum_{m=1}^M \sigma_m^* A_{pixel} \quad (7)$$

where σ_m^* is the complex conductivity of the tissue represented by the m^{th} grayscale pixel; M is the total number of pixels in the ankle cross-section and A_{pixel} is the area of a single pixel. A_{pixel} can be easily calculated by dividing the actual area of the ankle cross-section with M . Therefore, the axial current density J_z^n in the area represented by the n^{th} pixel can be approximated as

$$J_z^n = \sigma_n^* E_z = \frac{0.5 \sigma_n^* I_z}{A_{pixel} \sum_{m=1}^M \sigma_m^*} \quad (8)$$

Figure 8 shows the magnitude of the axial current density calculated using (8) for an incident electric field $E_0 = 1$ V/m r.m.s. illuminating the adult male human subject that was discussed in (Kibret et al., 2015). It can be seen that the highest current density occurred in the blood and muscle tissues, and the least occurring in the skin, fat, nerve, blood vessels, cortical bone and cancellous bone. Almost half of the current density in the muscle tissue exists in the connective tissues and tendons.

THE IMPLANTED TOROIDAL INDUCTOR

In the preceding section, we showed that a large axial current density is induced inside the muscle tissue. In order to collect this current for the purpose of implant wireless communication, a toroidal inductor that is clamped around a group of muscle fibers or a tendon in the ankle is assumed. Consider a toroid placed around the muscle tissue or tendons with the axis of toroid perpendicular to the cross-section of the ankle.

The toroid has inner radius r_1 , outer radius r_2 , and height h_t , as shown in Figure 9. An enameled

Figure 9. The half-section of the implanted toroidal inductor with ferrite core

Figure 10. The equivalent circuit of the toroidal inductor. C_{sh} is the parasitic capacitance between turns; R_w represents the loss in winding wire; L_{AC} is the internal inductance of the wire; R_{rad}^t is the radiation resistance of the toroid; R_c represents the magnetic core loss; and L_s is the self-inductance.

round copper wire of radius r_{cop} is wound around a ferrite core making N number of turns. In order to reduce the effect of leakage inductance, the inner wall of the toroid is completely covered by the copper windings. Thus, the number of turns was derived as $N \approx \pi r_1 / (r_{oop} + t_e)$ where t_e is the thickness of the enamel layer of the copper wire. The equivalent circuit representation of the toroid is shown in Figure 10.

THE PERFORMANCE OF THE WHOLE SYSTEM IN TRANSMISSION MODE

The operation of the system is similar to that of a current transformer; the toroid acts like the primary winding while the human body was approximated as a single turn secondary, as shown in Figure 11. The field induced inside the toroid core induces axial current in the tissue along the axis of the toroid. The representation of the human body as a single turn secondary describes more accurately a toroidal inductor clamped to the exterior of the ankle. The equivalent circuit of the ankle implant in transmission mode was approximated as shown in Figure 12. As a loop antenna, a toroidal inductor by itself has poor radiation efficiency (Balanis, 2005); therefore, we ignored its radiation resistance R_{rad}^t . The approximation of this setup to an implanted toroidal inductor is based on the result from (9) that large axial current density exists in

the muscle tissue which spans about 20% of the ankle joint cross-sectional area.

The equivalent circuit in Figure 12 consists of the equivalent circuit of the toroid in transmitting mode includes magnetic core effects, skin-effect and proximity-effect in the copper winding, and parasitic capacitance of the inductor

In Figure 12, Z_b is the sum of the impedances that represent the effects of the human body, the shoes, the ground and near-field coupling with nearby objects. Assuming the human subject is standing on a highly conductive ground plane and bare foot, Z_b can be approximated by the human body antenna impedance Z_A which is expressed in (Kibret et al., 2015) as the antenna impedance of the human body when the human subject is excited by a delta-gap electromotive force (emf) placed between the feet and the ground. The delta-gap emf was assumed to be equal to the emf induced by the implanted inductor, which is approximated by a current-probe feeding model.

Based on the analysis in (Kibret, 2015), Z_A can be expanded as $Z_A = R_{rad} + R_{dis} + jX_A$ where R_{rad} characterizes the power radiated P_{rad} ; R_{dis} characterizes the power dissipated inside the human body due to ohmic and dielectric loss of tissues; and X_A characterizes the near-field reactive power oscillating in the vicinity of the human body. From the expression of the resistance per unit length of the equivalent cylindrical antenna and from the definition of the radiation efficiency in (Kibret et al., 2015), the expression of R_{rad} and R_{dis} can be derived.

Figure 11. Visualisation of the lines of force in the human body forming the secondary loop

The circuit in Figure 12 can be simplified by transferring the secondary impedance to the primary as shown in Figure 13. Since the winding is assumed to completely cover the inner wall of the toroid, the magnetising inductance L_m was approximated by the self-inductance L_s of the toroid. The equivalent impedance seen by the transmitter Z_{eq} can be written as given in (9)

$$Z_{eq} = \frac{Z_s}{j\omega C_{sh} Z_s + 1} \quad (9)$$

where

$$Z_s = \frac{j\omega L_m (N^2 Z_A + R_c)}{j\omega L_m + N^2 Z_A + R_c} + R_c + R_w + j\omega L_{AC}.$$

Figure 12. The equivalent circuit of the implanted toroidal inductor. V_{in} is the input voltage of the transmitter; Z_o is the output impedance of the transmitter; L_m is the magnetising inductance referred to the primary side; and Z_B is the impedance of the human body and the surrounding

Figure 13. The simplified equivalent circuit of the implanted toroidal inductor in transmitting mode

Therefore, referring Figure 13, the radiation efficiency of the system η_r^t defined as the ratio of the radiated power P_{rad} to the input power P_{in} can be written as given in (10)

$$\eta_r^t = \frac{P_{rad}}{P_{in}} = \frac{|I_A|^2 N^2 R_{rad}}{|I_{in}|^2 \text{Re}(Z_{eq})} \quad (10)$$

The radiated power escapes into the surrounding using the human body as antenna. For simplicity, assuming the radiated power was emitted equally in all directions, the antenna gain of the system G can be approximated as

$$G(\text{dB}) = 10 \log_{10}(\eta_r^t). \quad (11)$$

The gain in the direction of the maximum emission can be approximated by that of a quarter-wave monopole antenna by adding 5.19 dBi to the value obtained from (11).

THE IMPLANTED TOROID INDUCTOR: AN ILLUSTRATIVE SCENARIO

Considering two implanted toroidal inductors with parameters shown in Table 1, the gain G calculated is shown in Figure 14. As can be seen in the table, the two toroids have a core thickness, $r_2 - r_1$ of 3 mm and a height h_t of 1 cm. The areas enclosed by the toroids are 0.64% and 2.16% of the cross-sectional area of the ankle joint considered in this study, which is indicated by the parameter A % in the table. The copper wire used was assumed to

be 20 AWG (American Wire Gauge) copper wire with enamel thickness of $0.25r_1$. It can be seen that the gain exhibits a broadband feature with the maximum occurring between 20 – 45MHz, which includes the resonance frequency of the human body. The resonance frequency of the human subject used for the two scenarios, which has height H_m and weight m given in Table 1, is near 40 MHz (Kibret et al., 2015).

The gain calculated using (11), was based on the assumption that only the human body impedance affects the current induced inside the human body. But, in reality, other factors, such as, the ground, shoes and nearby objects, affect the gain. When the impedance of 1 cm thick rubber shoes was added in series with the human body impedance Z_A , the calculated gain decreased by a maximum of 5 dB.

The given scenario can be further analysed by assuming an input current $|I_{in}|$ of constant magnitude. It was also found that more than 98.5% of the power was dissipated inside the magnetic core and a maximum of 1% of the power was absorbed inside the human body, with a negligible amount dissipating inside the wire, as shown in Figure 15. The radiated power was less than 0.5%. This suggests that the two important factors that determine the performance of the toroid are the parasitic capacitance and the magnetic core losses. Reducing these effects improves the efficiency of the system.

One way of reducing this capacitance is by increasing the separation of turns in the inductor. But this approach also introduces a leakage inductance that does not contribute to the axial current induced inside the enclosed tissue. As can be deduced from Figure 14, a toroid that

Table 1. Parameters of the system (Kibret et al., 2016)

Parameters	r_1 [mm]	r_2 [mm]	h_t [cm]	d [m]	r_{cop} [mm]	t_e [mm]	N	σ [S/m]	H_m [m]	m [Kg]	A%
Case 1	6.59	9.59	1	$\lambda/2\pi$	0.4	0.1	41	5.592×10^7	1.76	73	0.64
Case 2	11.28	14.292	1	$\lambda/2\pi$	0.4	0.1	70	5.592×10^7	1.76	73	2.16

Figure 14. The calculated gain for the two cases

Figure 15. The power loss percentage in the human body, the wire and the radiated power

has a minimised leakage inductance and smaller number of turns has a better performance than a toroid with larger number of turns. Therefore, the design of an efficient system calls for an optimized choice of the smallest number of turns that result in a reduced leakage inductance.

Assuming a transmitter of $EIRP=0$ dBm is located a distance of $d=\lambda/2\pi$ from the body, the power received P_{rec} on the load impedance $Z_L=50\Omega$ that is connected to the terminals of both inductors

is shown in Figure 16. As the received power is a function of the gain, the received power for toroid 1 is larger than that of toroid 2.

FUTURE RESEARCH DIRECTIONS

Experimental validations, as can be referred in (Teshome et al., 2016, and Kibret et al., 2015b), showed that the two techniques presented are not

Figure 16. The power loss percentage in the human body, the wire and the radiated power

only theoretical assertions, but also practical possibilities. As an immediate follow-up, the authors are working on transceivers that make use of the models presented in this chapter. The rising breakthrough in medical diagnostics and sensor technology demands more efficient implant transceivers. Most of existing implant-communication mechanisms are not tuned to this rising demand for medical implants and implant communications. Hence, low-power implant transmissions such as IBC and effective use of the human body as antenna needs further investigation in terms of transceiver coupling, powering systems and investigation of mitigation techniques for losses. The authors believe the results in this chapter could fill part of the knowledge gap in the field.

CONCLUSION

In this chapter two approaches are explored as alternative to existing implant communication techniques. A novel unified model for galvanically coupled IBC implant communication is presented. Analysis of the model shows that the technique is low power consuming, secure and offers a lower path loss compared to existing MICS based

implants for implant-to-implant and implant-to-surface setting. The second technique uses the human body itself as an antenna to radiate signals from the body to the outside environment. With proper mitigation of losses, the toroidal inductor provides a feasible feeding mechanism to utilise the body as an antenna.

KEY TERMS AND DEFINITIONS

Antenna: A device designed to radiate or receive electromagnetic radio waves.

Electromagnetic Models: Analytical and/or numerical models that describe propagation of electromagnetic signals through a medium.

Galvanically Coupled IBC: A type of intra-body communication where electric current is differentially coupled to the body using the anode and cathode electrodes implanted or mounted on the surface of the human body.

Human Body Antenna: The usage of the human body as an antenna to transmit or receive electromagnetic radio waves.

Implant Communication: A communication scheme where an electrical signal is transmitted to or from an electronic device implanted inside the human body.

Intra-Body Communication (IBC): Electric field communication using the human body as channel.

Wireless Body Area Network (WBAN): Signal transmission network of transmitters and receivers in, on and around the vicinity of the human body using the human body as part of communication channel.

Mobile Learning

E-Collaborative Learning (e-CL)

Alexandros Xafopoulos

University College London, UK

INTRODUCTION

Electronic collaborative learning (e-CL) is a highly topical issue in today's world of worldwide online communication. It can be regarded as a type of learning focusing on a specific learning method, collaboration, and a specific collaborative learning medium or resource, electronic technology (e-technology). The objectives of this article are to clarify the highly debated and promising concept of e-CL and its related terms, to provide insight in its process, and to present current, especially promising, trends.

E-CL appears new to the present digital age when employing digital technology, but its roots are found back in history as regards e-technology (Kock, 2008). The concepts and practices of collaboration and learning were evident in several forms from the beginning of human history and life.

BACKGROUND

Learning and Knowledge

To approach the meaning of e-CL the concept of learning must be examined. First of all, it should be noted that in this article human learning is considered although it may occur among other creatures, such as animals. Second, the concept of learning is interpreted by learning theories connected with the concept of knowledge. The hereby adopted interpretation of the learning process is as knowledge building, or creation or construction, following Scardamalia and Bereiter (2006).

To further explore the concept of knowledge, it is worth mentioning that there is a widely accepted progressive distinction of informative elements

into data, information, knowledge, and wisdom. At a data level there is isolated and meaningless information. Data are transformed into information when they acquire meaning. Information is enriched into knowledge or intelligence when it acquires situated context. Finally, knowledge is transformed into wisdom when it acquires personalised pragmatic context.

What is also worth noting is that four basic and increasingly difficult and important types of knowledge can be considered. Declarative, or factual or plain, knowledge regarding what, where, and when, as an instance; procedural or skill knowledge regarding how; conditional, or conceptual or structural or contextual or competence, knowledge regarding the previous in an interrelated context and regarding why; and finally, metacognitive knowledge or metaknowledge regarding cognition and knowledge (Krathwohl, 2002). The first two types may be characterised lower-order knowledge whereas the last two, the most valued, higher-order knowledge.

Collaboration

In addition, e-CL incorporates collaboration, which should be considered as a partnership community process, that is, the collaborating members share a sense of belonging, inclusivity, trust, and reciprocity as well as a common thinking and performing area. Moreover, the term collaboration is different from cooperation, since the former implies the construction of shared, mental or material, products to achieve a shared, mental or material, goal, for instance, problem solving, whereas in the latter each team member undertakes one part of the whole responsibility, constructs a separate product, combined with other members'

DOI: 10.4018/978-1-5225-2255-3.ch551

products in a later stage, and achieves a subgoal (Arvaja, Häkkinen, & Kankaanranta, 2008; Ertl, 2008; Laurillard, 2012).

Technology

Another e-CL fundamental notion is technology, which in general refers to any intended, mental or material, product of a mind-bearing being. In certain contexts it may be used to denote the digital technology. In this study it is used in the sense of e-technology, which can be analogue or digital, but with a great focus on the digital aspect used for collaborative learning purposes, which is more often and widely applied.

e-CL

Taking the previous conceptual descriptions into account one attempt to define learning is as the knowledge building process with knowledge building goals or objectives, and, in that sense, collaborative learning is regarded as the communicative shared-knowledge building process with shared-knowledge building goals. Following these, e-CL is considered as the communicative shared-knowledge building process with shared-knowledge building goals using networked electronic devices (Kock, 2008; Laurillard, 2012). The constructed shared knowledge is also referred to by the term 'collective intelligence'.

What is more, some discriminations are to be made. First, this study is concentrated on formal and not non-formal or informal learning. According to Werquin formal learning implies intended process and preset goals whereas non-formal implies intended process but non-preset goals and informal implies non-intended process and non-preset goals (Cameron & Harrison, 2012). Second, collaboration in learning differs from each of communication, interaction, discussion, inquiry, and practice in learning, although it may include them, by being a process involving management, iterative development, and agreements

to produce shared knowledge and outcomes based on it (Laurillard, 2012).

Third, this article focuses on digital devices, although the networked electronic devices do not necessarily imply computers, desktop or portable, but they may also be interconnected analogue electronic devices, such as, telephones or cameras (Kock, 2008). When computer networks are employed e-CL may appear as computer-supported collaborative learning (CSCL) applies. Finally, in the e-CL process several learning elements are identified. These are here distinguished into human, supportive, and framework elements and are examined below.

HUMAN ELEMENTS

In the e-CL process there are several roles of human participants or partners (Good & Robertson, 2006). They are usually considered and presented as communities or groups, although in lacking or trivial learning environments they may be constituted by only one person or be merged with each other. In large projects the communities may consist of several subcommunities and even create a structured hierarchy of nested communities. Furthermore, participants may be members of more than one community creating overlapping communities (Masterman & Vogel, 2007).

For the normal operation of the communities intra- and inter-community collaboration is essential. The participants in e-CL are also called stakeholders and the communities may be online or virtual, offline, face-to-face or real, or blended. Two frequently used terms, related to the e-CL process communities, are the community of enquiry (CoE) (Garrison, Anderson, & Archer, 1999) and the community of practice (CoP) (Wenger, 1998), which use enquiry and practice to achieve their goals, respectively.

The human elements are classified into the following communities; the management, the design, the implementation, the learning, the technology,

and other supportive communities (Xafopoulos, 2016). The management community determines the learning mission and overall learning aims, which must be implemented and followed by the other communities. The design community, following the general management community guidelines, undertakes the coordination, analysis, planning, and design of the e-CL process. The main role of the implementation community is the realisation of the e-CL process in actual settings. The learning community iteratively collaborates in order to build shared knowledge and artefacts.

Finally, supportive communities offer support to the e-CL process and may include technologists, funders, suppliers, maintenance staff, researchers, psychologists, neuroscientists, sociologists, anthropologists, linguists, philosophers, engineers, pastors, and guardians. The e-CL process can also be affected by people unsystematically or unintentionally interacting with the participants.

SUPPORTIVE ELEMENTS (TPACK)

Introduction

In the learning process of e-CL we may identify certain supportive learning elements. These are the learning media, or resources or technologies, the pedagogy or andragogy, the learning methods, including the way of communication and collaboration, and the learning content. The supportive elements may be categorised as being originally created, or being an adapted version, or just selected unchanged from another learning source. Following the technological pedagogical content knowledge (TPACK or TPCK) model or framework (Mishra & Koehler, 2006) three supportive elements could be identified. Technology, pedagogy, including methodology, and content.

Technology: Media

Technology incorporates media, applications, environments, and infrastructure. The appropriate

technologies are identified, combined, and applied for each e-CL learning environment. The presentation of the content through its several sensory forms, called modalities, requires the presence and function of certain devices or hardware called media, which substantiate it (Bezemer & Kress, 2008). There are several kinds of hardware supporting e-CL, for instance, digital and analogue mass media, desktop, mobile, and handheld computers, and mobile phones and devices.

Additional learning supporting hardware includes computer peripherals, such as cameras, projectors, speakers, and microphones, and other advanced tools, such as, advanced computer-mediated or augmented or virtual reality (VR) tools, interactive whiteboards (IWBs), digital wallboards, interactive transformable objects, multi-sensory and multi-touch devices, which interact with the participants in a variety of sensory ways, as well as robots.

Technology: Applications

The modalities can also be presented with the assistance of software applications. Several types of applications are used in combination with collaborative learning, which transform it into e-CL (Xafopoulos, 2016). The collaboration can occur real time in the same or different virtual room of these applications, which can be separated into web or web-based and non-web. The former ones gain increasing attraction and are divided into three generations (Xafopoulos, 2016).

Another distinction is between multimedia and non-multimedia, as well as interactive and non-interactive applications. Multimedia applications integrate some of the content modalities, whereas non-multimedia only a single content modality. The multimedia and interactive applications are increasingly widespread. Another category increasingly used in learning are mobile applications. Their considerable advantage is that they are usable in several places, even when moving or travelling. Finally, two applications which have attracted special interest in the educational

community are agents and avatars. They both are virtual humanoids, or even other kinds of creatures, created by programmers (Xafopoulos, 2016).

Technology: Environments

The applications and media can be integrated into electronic learning environments or platforms, such as, portals, social networks, virtual learning environments (VLEs) or learning management systems (LMSs), personal learning environments (PLEs), intelligent tutoring systems (ITSs), learning design environments, and massive online open courses (MOOCs) (Xafopoulos, 2016). Significant aspects that some of these environments support are learning content management, learner engagement, analytics and dashboards, and learning process capture. These learning environments can further be integrated into virtual worlds.

Technology: Infrastructure

The several kinds of networks and networking equipment, wired or wireless, are further technological elements supporting the learning process. These could be considered synonyms with the term information and communications technologies (ICTs). Another related concept is cloud computing for e-learning, that is, networks of remote servers and applications providing centralised storage and online access to e-learning services and resources (Dong, Zheng, Yang, Li, & Qiao, 2009).

Finally, certain digital technologies are supportive of the previously mentioned main technologies in the e-CL process, such as, user interfaces (UIs), which are studied by human-computer interaction (HCI), databases, knowledge bases, and search engines. These together with networks may be referred to with the term infrastructure.

Pedagogy: Learner Modelling

The pedagogy examines and proposes mainly about the human, and especially learner, model-

ling, about the learning objectives or goals or outcomes, and about the learning theories. It also proposes about the other supportive elements and serves as a basis to methodology which can be considered as part of pedagogy.

The learner modelling refers to the process of construction of learner models, that is, knowledge representations about learners. If the human models are accessible by the ones they model, and possibly also by other participants, they are called open. They may also be editable, interactive, and cooperative. The access takes place through an appropriately developed interface, such as, skill meters or concept maps. The represented knowledge is both static, which is also called profile, and dynamic, and usually significantly qualitative. For the learner modelling several kinds of participant aspects must be investigated (Xafopoulos, 2016).

Pedagogy: Learning Objectives

As regards the learning objectives or outcomes they refer to the desired results of the learning procedure given the status of the learning elements. The objectives may be structured in several layers from the more general and long-term, for example, final or institutional objectives, to the more specific and short-term ones, such as, activity objectives.

The more specific objectives are expressed using actions, conditions, regarding the human and supportive elements except the pedagogy, and criteria, regarding the framework elements and correctness levels. The actions, and the objectives including them, can be distinguished into cognitive, affective, and psychomotor ones according to the domains described in Bloom's taxonomy of learning objectives. The cognitive objectives can be classified in the 24 cells of the taxonomy table described in (Krathwohl, 2002) with a six-column cognition horizontal dimension and a four-row knowledge vertical dimension. One kind of criteria are the SMART ones (Doran, 1981), that is, to be specific, measurable, achievable, relevant or interesting, and time-bound.

An example of a significant general objective in the learning process is that the learner should advance to reach the limits of their capabilities, acquire metalearning and metacognitive skills, that is learn how to learn and think, and become both an autonomous and a collaborative flexible learner.

Pedagogy: Learning Theories

The theories investigate the way that learning is achieved, adopt certain principles, and propose learning techniques. They are considered of great importance in the design of a learning process. The major classes of learning theories are behaviourism, cognitivism and its variations, constructivism and constructionism, and social theories, which expand on the two latter with several variations (Xafopoulos, 2016).

Although instances of behaviourism, cognitivism, cognitive constructivism and constructionism are also applied in the e-CL process the most influential learning theories underpinning e-CL are social theories, such as, constructivism, communal constructivism, social constructionism, and distributed and situated cognition due to their collaborative background (Holmes & Gardner, 2006). Nevertheless, a blended approach regarding the theories, that is, selecting, or even combining, more than one theory according to each special occasion and objective, is what is usually applied in practice.

Methodology: Introduction

The methodology, taking into account the other supportive elements, and mainly pedagogy and the affective status of the learners, examines and suggests about the learning policies, techniques, and activities (Xafopoulos, 2016). The policies regulate the learning process, for instance, the kind of communication and collaboration inside and among communities, the community size, the level of formality and the prioritization and leadership among stakeholders. Methodological

principles are called strategies. The techniques are proposed, by underpinning learning theories and policies, routes leading to learning, such as the flipped classroom. Barkley, Cross, and Major (2014) proffer a classification of collaborative techniques depending on their focus; for example, performing, problem-solving, discussing, writing, drawing or constructing, and playing.

Methodology: Activities

The activities are implementations of the techniques in a specific learning environment. They can be substantially classified into presenting, involving presentation from the learning environment to the learner, and performing, involving learner performance in the learning environment. Among the numerous other types of activities some important distinctions are between electronic and not, collaborative and not, and linguistic or not. As for the electronic activities they can be further distinguished into online and not. With regard to linguistic activities the presenting include reading and listening, and the performing writing and speaking. In respect of the non-linguistic the presenting activities include the five basic human senses and the performing the physical movements.

A further possible categorisation of the activities would be the one according to the revised Bloom's taxonomy of learning objectives, which could also be applied to characterise activities, especially the cognitive domain taxonomy using the taxonomy table (Krathwohl, 2002). According to the latter taxonomy there are six increasingly difficult cognitive skills. The three lowest, that is remember, understand, and apply, are characterised lower-order thinking skills (LOTS) while the three highest, analyse, evaluate, and create, higher-order thinking skills (HOTS). The latter are most valued in learning environments and a particularly interesting expansion of them are those including multimedia, multiple interaction, collaboration, and HOTS. These can be termed MICH activities.

It is also noteworthy that certain activities, such as, exploratory, may combine several of the previously mentioned types. Moreover, in order that the activities are successful they must include clear and assistive descriptions and instructions regarding the learning process and environment. Finally, support actions could also be considered a kind of activities, which are usually undertaken by the implementation community to support the learning community (Sloep, Hummel, & Manderveld, 2005).

Content

The learning content corresponds to an aspect or subdomain of a learning subject and may expand to whichever area, or domain or discipline or subject, of study. The subdomain may be a simple or complex one. It can be classified into the four kinds of knowledge (Krathwohl, 2002). Furthermore, it should be modelled using a domain knowledge representation scheme. The content creation process must follow certain pedagogical criteria and a decisive factor for it is the learning community knowledge.

The learning content may appear in certain modalities, that is, culturally-shaped perceivable content forms (Bezemer & Kress, 2008). They are text, audio, such as speech, music, or other kind of sound, image, either photograph or graphic, animation, and video. There are three main ways the modalities are perceived by learners corresponding to three human senses; the visual, the auditory, and the tactile or haptic.

To advance learning the design and implementation members must possess, on the one hand, state of the art domain knowledge and, on the other hand, the skill to transform and represent this knowledge to the learning level of the learning community members using modalities and technological media so that the latter community may be assisted to explore this information and construct domain knowledge itself.

FRAMEWORK ELEMENTS

In the e-CL process there are certain framework or contextual elements, which usually play a secondary role in the process. The most basic of them are first time, in terms of point, duration, frequency, and temporal context, second space, in terms of location, area, settings or physical environment, and spatial context, and third society, in terms of sociocultural environment and context. These elements should be modelled in the learning design.

The e-CL approaches can be classified in terms of the framework elements time and space as follows. Firstly, as regards space they can be implemented either in a learning, physical or virtual, room, or in a distance, which can be further discriminated into long distance and short distance ones, or both in a learning room and in a distance, either in parallel or in different occasions, called blended or hybrid. The latter are the most suggested course of action for effective learning.

Secondly, regarding time the e-CL approaches can be implemented either in the same time, called synchronous or live or real-time, or in different time, called asynchronous or on-demand, or both in the same and in different time, in parallel or in different occasions, which let be called semi-synchronous.

As regards society, environments where e-CL could be applied are enterprises, the industry, e-commerce, entertainment, the arts, journalism, engineering, e-science, medicine, lower, higher and special education, and research.

e-CL PROCESS

Process Modelling (ADDIE)

The elements previously mentioned participate in, support, and frame the e-CL process, respectively. This process has been modelled in several ways called learning models. One of the most

frequently followed model is ADDIE (analysis, design, development, implementation, evaluation) (Branch, 2009; Branch & Merrill, 2012), which has several variants (Xafopoulos, 2016). Its acronym comprises the first letters of its five phases. When the phases are implemented through e-technology they can be characterised as e-analysis, e-design, e-development, e-implementation, and e-evaluation.

ADDIE Phases

The five phases of ADDIE, although in general terms are ordered, are not strictly sequential, but there may be several directions among them, such as, iterative cycles or spiral, backwards, overpassing and others, resulting in a dynamically iterative process, which may also be longitudinal (Branch & Merrill, 2012). There is often the need to practice more than one, or even all five, phases concurrently (Branch, 2009).

Analysis

To begin with, the problem, domain, goal, and human elements are specified at a preparatory phase, followed by the analysis phase, where the human elements are analysed and a needs analysis or assessment is conducted, generally specifying the rest learning elements supporting the learning needs. The analyses conducted can be distinguished into qualitative and quantitative ones. The latter are referred to as learning analytics, including prediction, structure discovery, and relationship mining (Baker & Siemens, 2014). In the present focus on e-CL collaborative or social learning analytics are of special importance (Ferguson & Shum, 2012). A useful graphical representation of their results capturing the learning dynamics are learning sociograms.

Design

At the design phase, where the analysis phase is taken into account, there can be a distinction of three subphases. First, the modelling design sub-

phase, where human and community models or profiles, whose descriptive form is called persona, as well as, policies, general and specific objectives, and content are designed based on underpinning learning theories. Second, the implementation design subphase, where implementation issues related to communities, such as group formation, technologies, techniques, activities, and framework elements are designed.

Third, the assessment design subphase, where assessments, that is, evaluative criteria and activities of the learning procedure, as well as other kind of evaluations, are designed. These assessments should be aligned with the learning objectives and activities. This correspondence or alignment among objectives or outcomes, activities, and assessments is termed 'constructive alignment' (Biggs & Tang, 2011). A detailed formal definition of a learning design is called a prototype. Finally, it should be noted that the design phase and its subphases are not strictly sequential but usually follow a spiral form, being reflective.

Development and Implementation

At the development phase the designed elements are practically deployed and at the implementation phase the developed e-CL process is performed with specific learning elements. Analyses like the ones performed in the analysis phase are usually performed in the implementation phase with an evaluative instead of a preparatory purpose. When these analyses are employed continuously over a time period they are referred to as tracking. Their result may be used as feedback to readjust the learning environment.

Evaluation

At the evaluation phase several evaluations of the implementation are executed. The analyses performed in the analysis and implementation phase are evaluatively extended and complemented in the evaluation phase. The evaluation appears in three forms. Generic evaluation, with general

characterisations of the outcome; assessment, checking against determined assessment criteria; and feedback, offering explanatory assistive and improving comments or reports. An assessment example is learning performance assessment, that is, the estimation of the degree of learning outcomes achievement against the assessment criteria, often including marking schemes.

A further usual categorisation of evaluation, according to the time it is performed, is into the three types of diagnostic or placement, formative, and summative, which evaluate before, during, and after the learning process, respectively (Miller, Linn, & Gronlund, 2009). Diagnostic evaluation is discriminated in some contexts to express the diagnosis of difficulties during learning (Miller et al., 2009).

The evaluation lately often is proposed to include formative feedback to the communities and actually does, so that they identify learning difficulties and overcome them. The time and way of feedback, especially formative, is of great importance for supporting learning. For instance, timely personalised formative feedback enhances the learning experience.

Another commonly used classification of evaluation, according to the way it is performed, is into criterion-referenced, normative, and ipsative. The first evaluates a learner's, or even a learning group, performance against specific evaluation criteria, the second against the other learners' performance, and the third against the learner's previous performance.

Design Element Hierarchy

What is of utmost importance in the design process is the hierarchy of the elements of the learning process. In other words, determining the amount of design effort and care to be provided in the interests of each of the human, the supportive, and the framework elements. For example, according to the hierarchy the learning design approach may be implementation-community centred, learning-community centred, content centred,

outcome centred, method centred, or blended (Selwyn, 2011).

Another serious concern in the design process is whether, how, and how much each of the participants in the learning process will participate in the design process. A highly esteemed among designers learning design approach, involving learners at different stages of the design process of a learning environment and supporting e-CL, is participatory design (PD) and its collaborative variant collaborative participatory design (CPD) (Xafopoulos, 2016).

FUTURE DIRECTIONS

The current 21st century has been predominantly termed in the sociological literature as the age of late modernity, which is characterised by uncertainty and worldwide radical changes. Therefore, it is too challenging to definitely predict and present the future of e-CL, which, nevertheless, appears to be very promising.

The future trends that can be diagnosed given the current circumstances are web integration; worldwide open access; enhanced learning analytics; learner-centred and partnering design; interactive and experiential, multimedia, situated and immersive, deep and multicultural learning; e-inclusion and personalisation; frequent personalised formative feedback; virtual learning worlds and MICH activities; and augmented online collaboration. Another emerging direction is the consideration of the learning environment as a self-organised, adaptable, and evolving ecosystem including diverse collaborating or antagonising entities or elements (Dong et al., 2009).

CONCLUSION

This article explored the highly topical and key issue of e-CL in a holistic overview. First of all, a clarification of the term and context of e-CL was provided comparing it with similar concepts and

analysing relevant concepts. The terms learning, knowledge, collaboration, collaborative learning, technology, e-technology, and e-CL were explored. Second, the human elements of e-CL were examined, together with their roles and aspects in the learning process. These elements were classified into main communities and secondary supportive communities.

Third, the supportive learning elements were visited, with a focus on each of them. Initially, on the technology, with a representative presentation of its numerous type of media, applications, environments, and infrastructure. Consequently, the article focused on the pedagogy, with an examination of the learner modelling, the learning objectives, and the major learning theories identifying the e-CL supportive ones. Furthermore, the methodology was visited, with an emphasis on the activities. And finally, the learning content and its modalities were explored.

Fourth, the framework elements time, space, and society were described and a classification of e-CL approaches according to them was provided. Fifth, the e-CL process was examined following the ADDIE model, analysing its five phases, and also visiting the design element hierarchy. Finally, future directions of e-CL were considered. Throughout the article key and significant approaches, methods, and terms were pinpointed and concisely developed.

Concluding, in the light of this study e-CL appears as a promising field for research, design, innovation, as well as creative and effective implementation. It proffers some of the most contemporary opportunities and challenges in terms of learning, collaboration, and technology, and therefore requires rigorous research, study, and experience to leverage its facilities.

KEY TERMS AND DEFINITIONS

ADDIE Model: A widely used framework which models the evolution of a learning process following spirally, that is revisiting the previous, the five phases of analysis, design, development, implementation, and evaluation.

Collaborative Participatory Design (CPD): A learning design approach where the learners collaborate potentially in every phase of the dynamically iterative and reflective learning process informing its design.

Computer-Supported Collaborative Learning (CSCL): The communicative shared-knowl-

edge building process with shared-knowledge building goals supported by a computer network.

E-Collaborative Learning (E-CL): The communicative shared-knowledge building process with shared-knowledge building goals using networked electronic devices.

Learning Design: The design of a learning process in three spirally-followed phases called modelling design, implementation design, and assessment design.

Multimedia Multi-Interactive Collaborative Higher-Order Thinking Skills (MICH) Activities: Learning supporting activities using multiple modalities, being interactive in many ways, being collaborative, and employing analytical, evaluative, and synthetic skills.

Technological Pedagogical Content Knowledge (TPACK) Model: A framework arguing that a combination of three kinds of knowledge is needed by the design and implementation members; technological, pedagogical, including methodological, and content knowledge.

Learning With Mobile Devices

Helen Crompton

Old Dominion University, USA

John Traxler

University of Wolverhampton, UK

INTRODUCTION

Mobile devices are being used to extend learning in both the global north and the global south. The launch of the International Journal of Mobile and Blended Learning is one of several indicators that mobile learning globally is reaching a critical and sustainable momentum and identity. The past decade has seen a host of pilots and initiatives across sectors and across countries. Mobile learning is being used to extend pedagogies to develop new ways of learning more aligned to empirical understandings of how students learn. Mobile learning is also taking learning to individuals, communities and countries where access to learning was challenging or problematic.

Environmental factors have meant that this development has often been haphazard. As researchers try to examine these new learning opportunities they are faced with a set of methodologies that were developed for use with tethered technologies with learning and evaluation methods being static (Sharples, Sanchez, Milrad, & Vavoula, 2009). In mobile learning context can vary significantly. This has expanded the field of mobile learning to have researchers examining learning that happens in a formal typical educational setting, non-formal non-intended serendipitous environments (Crompton; 2013a), and informal atypical settings (e.g. museums and science centers: National Research Council, 2009). With learning that happens in personal contexts, the researcher has the added difficulty in collecting valid research data

without interfering with the learning happening in those contexts Beale's (2007). This is becoming increasingly difficult in recent years with the pervasive ubiquitous nature of the devices today.

As the scholarly understanding of mobile learning is still relatively new and emerging, the mobile learning community is also now faced with broader challenges of scale, durability, equity, embedding and blending in addition to the earlier and more specific challenges of pedagogy and technology, but these developments take place in the context of societies where mobile devices, systems and technologies have a far wider impact than just mobile learning as it is currently conceived.

BACKGROUND

The concept of learning with small portable computers was developed by Alan Kay in 1972. Since that early conception, scholars, such as Traxler, Sharples, and Soloway are the pioneering scholars who have paved the way to a better understanding of the philosophical, pedagogical, and conceptual underpinnings of mobile learning today. Kay began with the initial idea of a portable device for learning. Traxler, Sharples and colleagues have explored the emerging theoretical frameworks of mobile learning to provide us with a better understanding of this field. Soloway and Norris have focused their work on how the affordances of mobile learning can extend traditional classroom pedagogies.

Defining Mobile Learning

We need to define what we mean by ‘mobile learning’, not merely as a way of establishing a shared understanding but also as a way of exploring the evolution and direction of mobile learning and as a way of identifying the community of practitioners and researchers. In discussing how we define mobile learning we address many wider issues in terms of explaining, understanding and conceptualising it.

‘Mobile learning’ is certainly not merely the conjunction of ‘mobile’ and ‘learning’; it has always implicitly meant ‘mobile e-learning’ and its history and development have to be understood as both a continuation of ‘conventional’ e-learning and a reaction to this ‘conventional’ e-learning and its perceived inadequacies and limitations. Over the last ten or so years this ‘conventional’ e-learning has been exemplified technologically by the rise of virtual learning environments (VLEs) and the demise of computer assisted learning (CAL) ‘packages’, and pedagogically by the rise of social constructivist models of learning over the behaviourist ones, by the growth of the learning object approach, by expectations of ever increasing multi-media interactivity and of ever-increasing power, speed, functionality and bandwidth in networked PC platforms. These are some of the points of departure for mobile learning. They refer back to ‘conventional’ e-learning and perhaps this is the mark of early ‘mobile learning immigrants’ and not the mark of the growing number of ‘mobile learning natives’.

We have to recognise that attempts at identifying and defining mobile learning grow out of difference, out of attempts by emergent communities to separate themselves from some older and more established communities and move on from perceived inadequate practices. Interestingly, at the first mLearn conference in the spring of 2002, in Birmingham UK, a key-note speaker predicted that mobile learning would have a separate identity for perhaps five years before blending into general e-learning. This has still yet to happen and mobile

learning continues to gain identity and definition rather than lose it.

Irrespective of the exact definition, personal mobile and connected technologies, including handheld computers, personal digital assistants, camera phones, smartphones, graphing calculators, personal response systems, games consoles and personal media players, are ubiquitous in most parts of the world and have led to the development of ‘mobile learning’ as a distinctive but ill-defined entity (see for example the reviews by Cobcroft 2006, and Naismith et al. 2004).

Early approaches at defining mobile learning focused on technology, for example saying it was “any educational provision where the sole or dominant technologies are handheld or palmtop devices” (Traxler, 2005), or on the mobility of the technology, describing mobile learning as, “elearning through mobile computational devices: Palms, Windows CE machines, even your digital cell phone.” (Quinn, 2000). Another view of mobile learning says it involves: “Any sort of learning that happens when the learner is not at a fixed, predetermined location, or learning that happens when the learner takes advantage of learning opportunities offered by mobile technologies” (O’Malley et al., 2003), whilst Desmond Keegan took a similar position in 2005, saying that the focus should be on mobility and mobile learning should be restricted to learning on devices which a lady can carry in her handbag or a gentleman can carry in his pocket. He defined mobile learning as ‘the provision of education and training on PDAs/palmtops/handhelds, smartphones and mobile phones and the characteristics of mobile learning is that it uses devices:

- Which citizens are used to carrying everywhere with them,
- Which they regard as friendly and personal devices,
- Which are cheap and easy to use,
- Which they use constantly in all walks of life and in a variety of different settings, except education.” (Keegan, 2005:3)

The MoLeNET initiative, a £6m programme across the UK vocational sector, still takes this approach, defining mobile learning as, “exploitation of ubiquitous handheld hardware, wireless networking and mobile telephony to enhance and extend the reach of teaching and learning” (MoLeNET, 2007). These definitions were too technocentric and imprecise. The transience and diversity of the devices, systems and platforms means that these definitions are also highly unstable. They merely put mobile learning somewhere on e-learning’s spectrum of portability (ending perhaps in ubiquitous, pervasive and wearable learning).

Whilst these attempts at definition use specific technical attributes to consolidate a definition of mobile learning in order to help us reason about it, other technical attributes, notably connectivity, usability and latency, have the very opposite effect and disrupt the notion that there is such a thing as mobile learning as an artifact of mobile technologies.

The uncertainty about whether laptops and Tablets deliver mobile learning – because of the lack of spontaneity in carrying them and starting them up - illustrates the difficulty with this kind of definition and the emergence of the UMPC (Ultra-Mobile PC) and netbook formats and the low cost XO systems will further trouble this boundary (Crompton, 2014a). They do however hint at the underlying challenge, that of conceptualising mobile learning in a way that recognises its origins and practices in specific technological systems but is abstract enough to be durable and to act as a stable platform for theorising about education and learning.

Crompton (2013b) looked beyond just the technical attributes to develop a definition of mobile learning from consolidating what she described as the four central constructs to mobile learning: pedagogy, technological devices, context, and social interactions. This resulted in mobile learning being defined as

“learning across multiple contexts, through social and content interactions, using personal

electronic devices” (p. 4). This is the most accepted current definition of mobile learning at this time, but will undoubtedly be modified in the future within this rapidly changing field.

CURRENT SCIENTIFIC KNOWLEDGE IN MOBILE LEARNING

There have been a few pioneering scholars in the field of mobile learning (e.g., Kay, Traxler, Sharples, Soloway & Norris) who have extended the literature in mobile learning. In the 1970s, Kay had the idea of developing a small portable device that students could learn from. Such a device did not prove to be feasible at that time, but due to more recent technological advancements, the mobile learning of today bears a good resemblance to Kay’s initial ideas.

As mobile learning started moving into fruition, scholars, such as Traxler and Sharples have provided us with an evolving theoretical framework that has enabled us to use gain a better understanding of this new form of learning. Soloway and Norris have focused on how mobile learning is changing the way students learn. While, the work of these scholars has significant overlap, for the purpose of this chapter, these two strands (theories and pedagogy) have been dichotomized to provide a more in-depth look at each of these topics.

Kay’s Dynabook

In the 1970’s Kay (1972) created the concept model of the Dynabook, which he described as a personal computer for children of all ages. This personal computer would have a number of unique features:

Imagine having your own self-contained knowledge manipulator in a portable package the size and shape of an ordinary notebook. Suppose it had enough power to outrace your senses of sight and hearing, enough capacity to store for later retrieval thousands of page-equivalents of refer-

Table 1. Emergent categories from mobile learning

1	Technology-driven mobile learning – a specific technological innovation is deployed to demonstrate technical feasibility and pedagogic possibility, perhaps the iPhone and iPad.
2	Miniature but portable e-learning – mobile, wireless and handheld technologies are used to re-enact approaches and solutions found in ‘conventional’ e-learning, perhaps porting an established e-learning technology, such as the VLE or e-portfolio, onto mobile devices.
3	Connected classroom learning – the same technologies are used in a classroom setting to supported static collaborative learning, perhaps connected to other classroom technologies; personal response systems, graphing calculators, PDAs linked to interactive whiteboards etc.
4	Mobile training and performance support – the technologies are used to improve the productivity and efficiency of mobile workers by delivering information and support just-in-time and in context for their immediate priorities, roles and duties
5	Large-Scale Implementation – the deployment of mobile technologies at an institutional or departmental level to learn about organisational issues.
6	Inclusion, assistivity and diversity – using assorted mobile and wireless technologies to enhance wider educational access and participation, for example personal information management for students with dyslexia.
7	Informal, personalised, situated mobile learning – the same core technologies are enhanced with additional unique functionality, for example location-awareness or video-capture, and deployed to deliver educational experiences that would otherwise be difficult or impossible; for example, informal context-aware information in museum spaces.
8	Remote, rural and development mobile learning – the technologies are used to address environmental and infrastructural hurdles to delivering and supporting education where ‘conventional’ e-learning technologies would fail. This classification is not purely theoretical. It has implications for the objectives and methods of evaluation and for the techniques and objectives for implementation; it may also imply the presence or otherwise of different underlying models of pedagogy and learning.

ence materials, poems, letters, recipes, records, drawings, animations, musical scores, waveforms, dynamic simulations, and anything else you would like to remember and change. (Kay & Goldberg, 1977/2001, p. 167).

These ideas were a little beyond that time and the Dynabook was never created; however, those seeds of ideas were sown and mobile learning of today has surpassed Kay’s initial ideas of learning with a mobile device.

Theories of Mobile Learning

As mobile learning emerged from Kay’s ideas, Traxler, Sharples, and colleagues have further explored the theoretical underpinnings of their emerging field. Kukulska-Hulme and Traxler (2007) saw a number of emergent categories that come from reviewing the mobile learning literature, see Table 1.

These may be innovative or conservative technically or pedagogically by virtue of their place in the classification. Of course, this attempt to define

mobile learning by making instances – definition by denotation rather than by connotation as we tried earlier – is potentially problematic since in choosing the instances we create a circular definition but it nevertheless takes us a bit further forward. Niall Winters (2006) provides a similar taxonomy which gives us an additional perspective on what might characterise different types of mobile learning, saying, “Current perspectives on mobile learning generally fall into the following four broad categories: (1) Technocentric. This perspective dominates the literature; (2) Relationship to e-learning. This perspective characterises mobile learning as an extension of e-learning; (3) Augmenting formal education; and (4) Learner-centered.” This echoes our earlier points. Another classification of mobile learning that might help us towards a definition is due to Naismith et al. (2004) who suggest that mobile technologies can relate to six types of learning, or ‘categories of activity’, namely behaviourist, constructivist, situated, collaborative, informal/lifelong, and support/coordination. The mobile learning may be manifest in the following ways: For behaviourist-type

activity, it is the quick feedback or reinforcement element, facilitated by mobile devices, that is most notable; For constructivist activity, mobile devices enable immersive experiences such as those provided by mobile investigations or games; For situated activity, learners can take a mobile device out into an authentic context, or use it while moving around a context-aware environment in a specially equipped location such as a museum; For collaborative learning, mobile devices provide a handy additional means of communication and a portable means of electronic information sharing; For informal and lifelong learning, mobile devices accompany users in their everyday experiences and become a convenient source of information or means of communication that assists with learning, or records it on the go for future consultation; Support, or coordination of learning and resources, can be improved by the availability of mobile technologies at all times for monitoring attendance or progress, checking schedules and dates, reviewing and managing, activities that teachers and learners engage in at numerous times during the day.

An attempt by Sharples, Taylor and Vavoula (2005:4) suggested that a theory of mobile learning should be assessed against the following five criteria as in effect their perspective on the defining characteristics of mobile learning: (1) Is it significantly different from current theories of classroom, workplace or lifelong learning? (2) Does it account for the mobility of learners? (3) Does it cover both formal and informal learning? (4) Does it theorise learning as a constructive and social process? (5) Does it analyse learning as a personal and situated activity mediated by technology?

Ann Jones (Jones et al 2006) makes a similar contribution based on the motivational or affective aspects of mobile learning as defining characteristics. These are both important in themselves and often cited anecdotally as major factors behind decisions to deploy a mobile learning strategy. They are control (over goals), ownership, fun,

communication, learning-in-context, and continuity between contexts.

There have also been attempts to define mobile learning and thus to distinguish it from 'conventional' e-learning in terms of the learners' experiences. One view (Traxler, 2006) in looking at characterisations of mobile learning found in the literature finds words such as 'personal', 'spontaneous', 'disruptive' 'opportunistic', 'informal', 'pervasive', 'situated', 'private', 'context-aware', 'bite-sized' and 'portable'.

These are contrasted with words from the literature of 'conventional' e-learning such as 'structured', 'media-rich', 'broadband', 'interactive', 'intelligent' and 'usable'. We can use these to make a blurred distinction between mobile learning and 'conventional' e-learning. However, this distinction, based on the learners' experiences of the two different modes of learning, misses a greater distinction. 'Conventional' e-learning nearly always takes place in situations where the learners' time and space have been dedicated and committed to e-learning, facing their computer, sat with their back to the world, with e-learning taking centre-stage (Crompton, 2013a).

Mobile learning in the sense that we have been talking about it takes place woven into a host of daily tasks, places, groups, interactions and situations. The associations that learners generally have with these two technologies, the static and the mobile, must also be vastly different. This distinction based around learner experience is however not only blurred but in part is also only temporary.

Many of the virtues of 'conventional' e-learning are the virtues of the power of its technology (and the investment in it) and these virtues will be accessible to mobile devices too as market forces drive improvements in memory size, interface design, processor speed, battery life and connectivity bandwidth. Nevertheless, this approach underpins a definition of mobile learning in terms of the learners' experiences and an emphasis on 'ownership', informality, spontaneity, mobility

and context that will always be inaccessible to 'conventional' e-learning. We should add that the reported learner experience of mobile learning may depend on where the specific project fits into the earlier taxonomy.

The communities cohering around mobile learning may still feel the need for a theory of mobile learning as well as a definition, for example because of the ability of theory to define a research agenda or produce useful predictions and generalizations (although in a postmodern era, the role of theory as an informing construct is under threat). Such a theory may however be particularly problematic since mobile learning is an inherently 'noisy' phenomenon where context is everything and confounding variables abound, and if theory is something generated by abstracting upwards from practice and experience, then perhaps mobile learning has yet to reach the critical mass of experience and practice that justify such abstraction and has been too fragmented to justify transferable generalisations.

The work of Kuhn (1962) on the structure of intellectual change provides some insights into the role of 'theory' in relation to the professional activities of researchers (though not one without its critics) 'Conventional' e-learning has certainly gained credibility and status from the work of, for example, Laurillard (2002) and Salmon (2000) but there is currently insufficient work in mobile learning generally to underpin much theory building. Theories of 'conventional' e-learning rest on the experience of stable technology platforms; the dominant and enduring nature of Windows, QWERTY, IP, HTML and WWW means that theorising about 'conventional' e-learning can take place in a technology environment that is consistent, homogeneous and transparent – the technology no longer gets in the way. The technology platform upon which mobile learning theory might rest is by comparison volatile, inconsistent and haphazard and so must impede the work of understanding mobile learning itself. Mobile learning needs a 'theory of technology'. We could argue that the mobile learning community in look-

ing for theory is – to oversimplify – faced with three different options and dilemmas: (1) Import theory from 'conventional' e-learning and worry about transferability, (2) Develop theory *ab initio* locally and worry about validity, and (3) Subscribe to some much more general and abstract theory and worry about specificity and granularity.

Diana Laurillard's recent recognition of the impact of mobility and mobile technologies on the Conversational Framework (Laurillard, 2007) is an example of taking the first option. She discusses the possibilities of increasing interaction between the learner and the environment but also how problematic or unproductive this might be in informal learning or unsupervised learning (for example, in museum spaces) where a teacher is neither in a position to set appropriate tasks nor to provide meaningful feedback.

This is within more general remarks about the use of the Conversational Framework to support "a rigorous approach to working out how to support all the component learning activities, in remote locations, with learners guided only by the tasks set, the information available online, the characteristics of the world they are in, and peer support." This is a case of mobile learning looking to challenge and extend an accepted e-learning theory. The emerging theories of 'connectivism' (Siemens, 2004) and 'navigationism' (Brown, 2005) are nearer to the second option.

People are now learning "through communities of practice, personal networks, and through completion of work-related tasks" in an environment in which "know-how and know-what is being supplemented with know-where (the understanding of where to find knowledge needed)" (Siemens, 2005). Thirdly, it is fair to say that many of the more theoretically inclined members of the mobile learning community (see for example Sharples et al, 2005) subscribe to versions of Yrjö Engeström's 'Activity Theory' (1987) and this would be the most obvious example of the third option, an analysis of much purposive human activity. Engeström and his colleagues refers to Activity Theory as a "commonly accepted name

for a line of theorizing and research initiated by the founders of the cultural-historical school of Russian psychology.” whilst others (Er and Kay, 2005) say that the underlying philosophy of the theory is to explain human activity and behaviour.

Learning is analysed as a cultural-historical activity system, mediated by tools that constrain and support the learners in their goals of transforming their knowledge and skills. This is not an attempt to explain or assess Activity Theory but merely to position it as a broad and abstract account of more than just learning and technology. Returning to the issue of definition, Josie Taylor (2006) comes at it from a high level, seeing the question as whether ‘mobile learning’ signified a) learning mediated by mobile devices or mobility of learners (regardless of their devices), or b) mobility of content/resources in the sense that it can be accessed from anywhere.

In this account her audience preferred the broader concept of learning taking place in the ‘mobile age’, rather than the use of the narrower term ‘mobile learning’. Focusing on defining mobile learning in an age where actually nothing stays still is perhaps missing the point; the question, ‘what is mobile learning?’ must be replaced by the questions, ‘what is learning in a mobile age?’ or perhaps ‘what is mobile learning?’ Our societies are changing as mobile devices, systems and technologies become universally owned, accepted and used, and as a consequence the meaning and significance of learning are changing too. Perhaps ‘learning with mobile devices’ was adequate all along.

Extending Pedagogies

In the early 2000’s, Soloway and Norris (2003a, 2003b, & 2004) called for educators to see beyond 1:1 computing with laptops and to consider the use of personal computers that can fit into the palm of their students’ hands. These devices would revolutionise learning. This change is evident today as mobile learning is extending the boundaries of traditional pedagogies with learning that is

personalized, contextualized, and unrestricted by time and environment (Crompton, 2013a; 2014).

Mobile devices, and their technologies and systems, are eroding established notions of time as a common structure that had previously underpinned social organisation and the consensual understanding of the world. Time-keeping is being replaced by the ‘approx- meeting’ and the ‘multi-meeting’ (Plant, 2000), ‘socially negotiated time’ (Sørensen et al, 2002), the ‘microcoordination of everyday life’ alongside the ‘softening of schedules’ (Ling, 2004) afforded by mobile devices and Nyíri (2006:301) says, “with the mobile phone, time has become personalized”. Whereas previously our social and business relations had to be organized and synchronised by absolute clock time, now mobile technologies allow us to renegotiate meetings and events on-the-fly.

Mobile devices are also eroding physical place as a predominant attribute of space. It is being diluted by “absent presence” (Gergen, 2002), the phenomenon of physically co-located groups all connected online elsewhere—everyone in the room is online elsewhere - and “simultaneity of place” (Plant, 2002) created by mobile phones, a physical space and a virtual space of conversational interaction, and an extension of physical space, through the creation and juxtaposition of a mobile “social space”. Ironically, many conversations on the mobile phone, the device to demolish locatedness, start with, “I’m on the train”. Clearly we are still adjusting to the disembodied world of mobility.

Mobile devices are reconfiguring the relationships between spaces, public ones and private ones, and the ways in which these are penetrated by mobile virtual spaces. This is documented in the literature of mobilities, for example Plant (2000), Katz and Aakhus (2002), Ling (2004) and Brown et al (2004). Virtual space, and its tasks and relationships, that used be occupied by people sat down, monopolising their attention and partitioning them from the other people and the physical spaces around them moving, now moving amongst these other people and spaces and amongst other tasks and relationships.

This is accompanied by what goes on in those spaces; Cooper (2002) says that the private “is no longer conceivable as what goes on, discreetly, in the life of the individual away from the public domain, or as subsequently represented in individual consciousness”, Sheller and Urry (2003) argue “that massive changes are occurring in the nature of both public and private life and especially of the relations between them,” and Bull (2005) writing about the iPod says “The use of these mobile sound technologies informs us about how users attempt to ‘inhabit’ the spaces within which they move.

The use of these technologies appears to bind the disparate threads of much urban movement together, both ‘filling’ the spaces ‘in-between’ communication or meetings and structuring the spaces thus occupied.” Earlier work on the Sony Walkman came to similar conclusions, “the Walkman disturbed the boundaries between the public and private worlds” (Du Gay et al 1997: 115) Mobile devices are redefining discourse and conversation. Goffman (1971), for example, noted the phenomenon of ‘civil inattention’, where in certain situations it is customary not only to not speak to others but to avoid looking directly at others. This management of gaze is one way in which the boundary between public and private is negotiated and is now often a characteristic of creating a private space for mobile phone conversations in a public setting; a similar concept is the ‘tie-sign’, those signs that keep a face-to-face encounter live and ‘in play’ whilst servicing an interruption caused by a mobile phone call. The recipient of the call is obliged to “play out collusive gestures of impatience, derogation, and exasperation” according to Goffman. Murtagh (2002) describes a wide set of non-verbal actions and interactions with the mobile phone in public, and these are part of a wider transformation of discourse and social interaction as society engages with mobile technologies.

Alongside these evolving patterns of behaviour, mobile devices help communities and sub-cultures define themselves by affording new forms of

language, txt-speak being the obvious example of a language that helped its original users mark themselves out as different from non-users, usually their parents. Mobile devices are creating communities and groupings, sometimes transient and virtual ones, arguably at the expense of existing and traditional ones, captured in Howard Rheingold’s (2003) defining book. With these groupings come new norms, expectations, ethics and etiquettes (for example, see Ling (1997, 2004) for a discussion of ethics in a mobile context; and shifting ideas about the self and identity.)

Geser (2004:11) points out that, “the cell phone helps to stay permanently within the closed social field of familiar others: thus reinforcing a unified, coherent individual identity.” These are the contexts of ‘learning in a mobile age’. Clearly there is much here for educators and learning technologists to digest, from the changes in expectations and practices of interpersonal behaviour in the tutorial, seminar and lecture to the expectations of universities, schools and colleges in specifying the times and places to deliver education. Obviously, mobile devices, systems and technologies are also dramatically changing the economy, thus changing our ideas about artifacts and assets, and the jobs and organisations needed to create, distribute and trade them, and dramatically changing the nature of work itself. Educators must digest these too in their role preparing learners for employment.

Mobile devices, systems and technologies also have a direct and pervasive impact on knowledge itself, and how it is generated, transmitted, owned, valued and consumed in our societies. At the most superficial level, they do finally deliver on the ‘anywhere, anytime’ promise and apparently on other slogans too, namely ‘just-in-time’, ‘just-for-me’, ‘here-and-now’. These may be however less simple and benign than they seem. Firstly, knowledge is not an absolute. It has been argued that it is socially determined and socially constructed but it has also always been mediated by its container, its medium, its repository. Mike Sharples (2005:1) says, “Every era of technology has, to some extent, formed education in its own

image. That is not to argue for the technological determinism of education, but rather that there is a mutually productive convergence between main technological influences on a culture and the contemporary educational theories and practices.

The teacher is no longer seen as the holder of information but students are now provided with the opportunity to access this information for themselves (Norris & Soloway, 2011). In the era of mass print literacy, the textbook was the medium of instruction, and a prime goal of the education system was effective transmission of the canons of scholarship. During the computer era of the past fifty years, education has been re-conceptualised around the construction of knowledge through information processing, modelling and interaction. For the era of mobile technology, we may come to conceive of education as conversation in context, enabled by continual interaction through and with personal and mobile technology.”

The earliest formats, the book and the lecture, originally constrained knowledge to a linear format, the book having at least usually some facilities of graphics, review and organisation and more recently, computers provided web-based hyper-linked information. This was delivered with greater multi-media richness than books but in smaller chunks governed by the heuristics of usability and increased nonlinear navigational complexity. Mobile devices can now deliver information in far smaller chunks but with a vastly increased navigational overhead.

Clearly, these different formats must each have an effect on information and on knowledge in their different ways, on what is accessible and what is valued. With mobile devices, there is a concern that they serve up vast amounts of information and knowledge in small disconnected and trivial chunks. As T. S. Elliott (1934) said, “Where is the Life we have lost in living? Where is the wisdom we have lost in knowledge? Where is the knowledge we have lost in information?” Search engines and

knowledge bases can now serve up information that is uniquely customised to the user and their context, meaning their history, their location, their interests, their preferences and their environment.

Whilst this level of personalization seems attractive and desirable, there is also concern that knowledge and information become individualised, a ‘neo-liberal nightmare’ where each user exists in their own unique information world, fragmenting learners in a ‘fragmented society’, to use Bauman’s (2001) phrase in an accurate but narrower sense than he intended. User-generated content, meaning in user-generated knowledge and user-generated information, is widely available on mobile technologies. Google and Wikipedia, both now location-specific, are examples and they both allow learners control over what they learn, unmediated by any formal institutional learning.

They also allow learners to participate in creating learning through their contributions. This can take place through such systems as Wikipedia but most conspicuously with mobile technologies through the activity of citizen-journalism (Owen, 2005), where members of the public using camera-phones capture images of breaking news and post them straight onto shared file-spaces such as Flickr or YouTube. Journalism has been called the first draft of history and here we see it generated without the intervention of professional journalists or centralised and controlling organisations, perhaps from the perspectives of a mobile culture or particular mobile subcultures.

This generation of new knowledge intrudes a new protagonist into the debate and dichotomy between utilitarian and liberal views of education, and challenges the idea of a common curriculum or universal canon of accepted and useful knowledge that an education system must deliver. It challenges too formal learning, its institutions and its professionals, in their roles as society’s gate-keepers to learning and technology for disadvantaged individuals and communities.

CONCLUSION

This chapter puts the work and evolution of mobile learning into the broadest possible context and explores the significance of ideas about ‘learning in a mobile age’ in the context of the current development of mobile learning. The mobile learning community has an increasingly clear sense of its achievements and its direction but looking beyond the immediate community reveals a far more complex and changing situation. At this point, we can only sketch parts of the evolving picture, guess how society, its conception of learning and the role of mobile technologies in supporting that conception will fit together and wonder at the place of our current work. The challenge for the mobile learning community is the balance between facing inwards, to develop its work, and facing outwards, to understand the context and importance of that work.

FUTURE RESEARCH DIRECTIONS

In looking back at this chapter and attempting to revise it, the main sense and direction of it remains valid and true but a complementary and more critical account (Traxler 2010) sits alongside it. Taken together, these neatly encapsulate mobile learning research and its wider significance.

KEY TERMS AND DEFINITIONS

Mobile Learning: Mobile learning is defined as “learning across multiple contexts, through social and content interactions, using personal electronic devices” (Crompton, 2013, p. 4).

Pedagogies: Methods of teaching.

Personal Computers: Another term typically used to describe mobile devices.

Tethered Technologies: Digital Technologies that typically require a constant electrical source, such as desktop computers.

User Generated Content/Information: This term is used to describe content/information created by consumers or end –users, such as video, digital images, audio files, and blogs.

Mobile Game-Based Learning

Boaventura DaCosta

Solers Research Group, USA

Soonhwa Seok

Korea University, South Korea

Carolyn Kinsell

Solers Research Group, USA

INTRODUCTION

The use of video games to enhance learning has been the subject of fierce debate (Guillén-Nieto & Aleson-Carbonell, 2012). Nonetheless, experts have long strived to comprehend the draw of these games and their potential role in education. Thus, there is increasing interest in the application of video games in primary, secondary, and higher education; government; financial services; healthcare; hospitality; science and technology; telecommunications; and corporate and military training (Garris, Ahlers, & Driskell, 2002), to achieve a variety of learning outcomes (Kebritchi & Hirumi, 2008). To date, findings point to the instructional benefits of video games in the areas of computer science, geography, language, mathematics, photography, and science (DaCosta, Seok, & Kinsell, 2015).

Advancements in mobile computing have helped pave the way for new video game research (DaCosta & Seok, 2017a, 2017b) in different areas of interest, to include social development, intellectual activities (Spikol & Milrad, 2008), and general learning (Facer et al., 2004; Rogers & Price, 2006). The anytime-, anywhere-, and on-any-device characteristics of mobile technology are of particular importance because they offer new opportunities to research game-based learning (GBL) that is free from space and time restrictions (DaCosta et al., 2015). That is, mobile games have the potential to bridge the gap between the

classroom and the real world by placing students in authentic places and learning situations (Costabile et al., 2008). This has, in part, contributed to what is mounting research on what could be called *mobile game-based learning* (mGBL).

This chapter offers a review of the literature on mGBL. Extending the work of DaCosta et al. (2015), the discussion includes (a) a definition of mGBL in the context of game-based learning; (b) a review of the educational benefits of mobile games, building on what is known about video games and learning; and (c) identification of mobile game examples (called out in the literature) that have been experimented with and/or used to explore learning.

To ensure scholarly rigor, the research offered here was compiled in a staged approach similar to that of primary research (Cooper, 1998). The majority of the content comes from books, academic journals, and databases. While peer-reviewed materials were foremost, other resources were also used, including online articles, as supplemental information befitting their academic stature and to provide context regarding “practicing real world examples or an in-the-trenches view” (Kinsell, DaCosta, & Nasah, 2014, p. 161). Thus, this work presents the perspectives and findings of numerous scholars, practitioners, researchers, and experts in an effort to provide a well-rounded view of the educational possibilities of mobile games.

Throughout the chapter the term *video game* refers to a game played on a personal computer

(PC) or dedicated game device, such as a game console (e.g., Xbox®, PlayStation®, Wii®) or handheld game device (e.g., 3DS®, Vita®). The term *mobile game*, on the other hand, is used to refer to a video game played on a mobile device (e.g., cell phone, personal digital assistant [PDA], smartphone, tablet). Finally, this work is not intended to debate the practice of video games in education or the use of these games in classrooms, but rather to drive forward the study of mobile learning.

BACKGROUND

What Is Mobile Game-Based Learning?

While game-based learning is a fairly recognized notion, attempts at offering a thorough description have proven difficult (Perrotta, Featherstone, Aston, & Houghton, 2013). Many explanations often consist of definitions attempting to identify the key principles and mechanics involved (e.g., Perrotta et al., 2013). At its core, GBL is rooted in the belief that games can be used in the learning process. This means that GBL is less about the games themselves and more about the educational contribution they can make, with focus on the social dynamics involved and how to best use these games to enhance learning (Perrotta et al., 2013). Building upon this idea, mGBL may be understood as an extension of GBL, fixed in the belief that games played on a mobile device (e.g., cell phone, PDA, smartphone, tablet) can be used to enhance the learning experience.

What Do We Know About Mobile Game-Based Learning?

As mentioned, the educational value of video games has long been a topic of debate (Guillén-Nieto & Aleson-Carbonell, 2012). It should come as no surprise, therefore, that studies have reported mixed findings regarding the academic

impact of these games, with contradictory findings commonplace (Egenfeldt-Nielsen, 2006). One of the major factors contributing to the difficulty in offering detailed, consistent, and concrete evidence in support of the academic benefits of video games has been the nature of the studies themselves (Perrotta et al., 2013). For example, studies have varied in their aims, ranging from the impact of video games on learning outcomes measured in the contexts of academic achievement, cognitive performance, gender, attitudes toward learning using the games themselves, acquisition of knowledge and skills, motivation and classroom engagement, to types of learning and kinds of games. Studies have also examined the educational value of video games across different domains, such as civics and society, computer science, language, and mathematics (Perrotta et al., 2013). Further, diverse conceptual frameworks and learning theories have been adopted, encompassing behaviorism, cognitivism, and constructivism approaches (Egenfeldt-Nielsen, 2006). Finally, it has been noted that many of these studies are subject to methodological flaws and limitations (Perrotta et al., 2013), which, among other challenges, have included research bias, weak assessments, short exposure times, and lack of control groups (Egenfeldt-Nielsen, 2006).

Even with these mixed findings, wide range of study topics, and methodological flaws, the positive relationships between video games and learning (Egenfeldt-Nielsen, 2006; Perrotta et al., 2013) have been no less argued. It has been offered, for example, that video games are more flexible than other media, almost naturally supporting adaptive learning (del Blanco, Marchiori, Torrente, Martínez-Ortiz, & Fernández-Manjón, 2013). This has helped promote the idea that video games can play an important role in active learning, especially in terms of critical thinking skills, knowledge construction, collaboration, and effective use of and access to information and communication technology (Ellis, Heppell, Kirriemuir, Krotoski, & McFarlane, 2006). Moreover, because video games can provide immediate

feedback pertaining to actions and decisions (at times, within a complete and interactive virtual playing space), it has been proposed that ambient information can foster an immersive experience, stimulating interest in the game (Mitchell & Savill-Smith, 2004), and encouraging exploration and experimentation (Kirriemuir, 2002). This, in turn, can help promote authentic learning, allowing students to practice within a highly realistic but safe and risk-free environment (del Blanco et al., 2013). It has also been proposed that video games put the learner in a decision-making role by creating harder and harder challenges, allowing learning to occur through trial and error (Gee, 2007) or through the presentation of increasingly difficult challenges that are adapted to the learner's mastery of previously acquired knowledge and skills (Gentile & Gentile, 2008). Given this benefit, video games can be used to offer activities that are paced to the student's aptitude, thereby providing differentiated instruction (Paraskeva, Mysirlaki, & Papagianni, 2010). This allows knowledge and skills to be practiced to a mastery level, becoming automatized, and enables students to focus consciously on comprehending or applying new information (Gentile & Gentile, 2008).

These are not new ideas; acceptance that video games can be successfully used in learning dates back several decades. For instance, studies have suggested that video games can be used to (a) increase the retention of embedded instructional subject matter (Dempsey, Lucassen, Gilley, & Rasmussen, 1993; Jacobs & Dempsey, 1993; Pierfy, 1977; Ricci, Salas, & Cannon-Bowers, 1996) when teaching specific skills (Griffiths, 2002), to include algebra (Corbett, Koedinger, & Hadley, 2001), biology (Ybarrondo, 1984), photography (Abrams, 1986), and computer programming (Kahn, 1999); (b) develop higher-order cognitive skills (Wood & Stewart, 1987); and (c) work through personal problems (Bowman, 1982; Chaffin, Maxwell, & Thompson, 1982; Trinkaus, 1983). In addition, findings have shown improved performance on visual attention tasks (e.g., Feng, Spence, & Pratt, 2007; Green

& Bavelier, 2003, 2006), spatial abilities (e.g., Greenfield, Brannon, & Lohr, 1994), hand-eye coordination (e.g., Griffith, Voloschin, Gibb, & Bailey, 1983), reaction times (e.g., Goldstein et al., 1997; Orosy-Fildes & Allen, 1989; Yuji, 1996), and development of social skills among students with disabilities (e.g., Gaylord-Ross, Haring, Breen, & Pitts-Conway, 1984; Sedlak, Doyle, & Schloss, 1982).

Against this background, the body of knowledge on the educational value of video games continues to grow (Cogoi, Sangiorgi, & Shahin, 2006). This includes research focused on mobile computing. However, to date, research focused explicitly on GBL in the context of mobile games has predominantly centered on the technical capabilities of emerging mobile devices (e.g., Bell et al., 2006; Cheok, Sreekumar, Lei, & Thang, 2006; Göth, Häss, & Schwabe, 2004; Grant et al., 2007; Licoppe & Inada, 2006; Matyas et al., 2008; Naismith, Lonsdale, Vavoula, & Sharples, 2004; Schmitz, 2014; Sedano, Laine, Vinni, & Sutinen, 2007; Sotirou et al., 2008), with considerable attention placed on location-aware (i.e., Global Positioning System [GPS]) capabilities, in turn, offering new ways to embed learning in authentic settings. That is, digital content can be infused with the real world in an augmented reality (AR), blurring the boundaries between a virtual world and real life, resulting in a blended experience (De Freitas & Griffiths, 2008; Huizenga, Admiraal, Akkerman, & ten Dam, 2009; Montola, 2011). This mixed reality is incredibly important because it allows students to experience the real world, while at the same time, interact with virtual objects in a real space, in effect, taking students and learning out of the traditional classroom setting (Grant et al., 2007; Huizenga et al., 2009; Roschelle & Pea, 2002). In short, this offers educators new ways to help their students grasp relationships and connections (Yuen, Yaoyuneyong, & Jonhson, 2011). This mixed reality is also important because it is believed to provide students with a truly reflective experience (Price, Rogers, Scaife, Stanton, & Neale, 2003; Rogers, Scaife, Gabrielli, Smith,

& Harris, 2002; Sharples, Corlett, & Westmancott, 2002; Stanton, O'Malley, Ng, Fraser, & Benford, 2003). Altogether, these factors make mobile technology a well-matched platform for supporting learning activities (Klopfer, Squire, & Jenkins, 2002).

Examples of Mobile Game-Based Learning

DaCosta et al. (2015) identified mobile games found in the literature that have been used to integrate learning with aspects of the physical world. An expansion of their list is shown in Table 1. While not exhaustive, this compilation can be viewed as a starting point for those interested in examining mobile games that have been used to explore GBL in the context of mobile computing. Providing different experiences and learning contexts, these games demonstrate the educational potential of mobile computing. For example, some of these (a) demonstrate opportunities to align educational institutions more closely with local communities; (b) recreate historical events by placing learners in real-world situations and places as a way to immerse and motivate students, helping them learn about past people, locations, and events; or (c) show how place and time can be used to teach important concepts. The following are some specific examples.

In the augmented reality mobile game project *Mentira*, Holden and Sykes (2011) described how, using clues provided on an iPod Touch®, students practice their Spanish while solving the prohibition-era murder of Dionisio Silva by exploring various locations in the neighborhood of Los Griegos in Albuquerque, New Mexico. Along with moving learning outside of the classroom, the project sparked interest among residents, who were excited that students were going to be learning about their neighborhood. In another mobile game project, *Frequency 1550* (Huizenga et al., 2009), using GPS-capable smart video phones, students acquired historical knowledge of medieval Amsterdam by being placed in the city and

completing tasks at certain locations. Also moving learning outside of the classroom, this project demonstrated the use of authentic settings in the learning process. Colella (2000, 2002), in turn, showed how students can learn about the spread of infection using a classroom-based participatory simulation, in which they interacted with one another in a physical location using custom-built devices. Although the location was not necessarily of importance in this project (as it was in others), it demonstrated how concepts can be simulated with the aid of mobile devices in a physical space.

Other mobile games, found in the literature, are not necessarily educational or use location-based technology, but may be no less important to the discussion on mGBL. For example, the following games would not be considered pedagogical, but are unique in that they demonstrate the potential of mobile computing, with some demonstrating the use of time and place mechanics: *AlienRevolt* (de Souza e Silva, 2008), *BotFighters* (Sotamaa, 2002), *Can You See Me Now?* (Benford et al., 2006), *CitiTag* (Vogiazou & Raijmakers, 2004), *Epidemic Menace* (Lindt, Ohlenburg, Pankoke-Babatz, & Ghellal, 2007), *GeoCaching* (Groundspeak, 2016), *Human Pacman* (Cheok et al., 2004), *I like Frank* (Flintham, Benford, & Humble, n.d.), and *Uncle Roy All Around You* (Benford et al., 2004).

Whereas, the following games could be viewed from the perspective of mGBL, offering some level of instruction, but they do not necessarily take advantage of place-based technology or take advantage of this technology to the extent of some of the other games discussed thus far: *AKAMIA* (Ahmad & Rahman, 2014), *Eduventure* (Ferdinand, Müller, Ritschel, & Wechselberger, 2005), *GEIST* (Kretschmer, 2002), *iPlayCode* (Zhang & Lu, 2014), *MaCMoG* (Shiratuddin & Zaibon, 2001), *Mad City Mystery* (Squire & Jan, 2007), *Mobile Rhythm Learning System* (Wang & Lai, 2011), *The MOBO City* (Fotouhi-Ghazvini, Earnshaw, Robison, & Excell, 2009), *Weatherlings* (Sheldon et al., 2010), and *ZooQuest* (Veenhof, Sandberg, & Maris, 2012).

Table 1. Mobile games presented in the literature that have been used to integrate learning with aspects of the physical world

Title	Description	Purpose
<i>Blåtannkoden</i>	Players visit the Norwegian Oslo Norsk Telemuseum. Using their mobile devices, players photograph QR (quick response) codes, identifying solutions to riddles related to museum topics. Additional information about the topic is offered with correct answers, to include a letter. At the end of the game, letters form a secret word that can be used to get a free gift (Ceipidor, Medaglia, Perrone, De Marsico, & Di Romano, 2009).	Explore learning about history
<i>BuinZoo</i>	Players visit a zoo in central Chile and participate in a guided tour presented as a quiz game. In groups of four, players use a virtual map on a PDA to locate animals and digital resources to answer questions. Later in the classroom, players use a simulation to learn about evolution by preserving and developing three species of four classes (fish, amphibians, reptiles, and birds) (Sánchez, Salinas, & Sáenz, 2006).	Explore learning about species and classes
<i>Capture the Flag</i>	Players track flags in an AR environment that combines play with PC-based visualizations and mobile digital flags (Cheok, Sreekumar, Lei, & Thang, 2006).	Explore active game play
<i>CitiExporer</i>	Players take geo-referenced photos, localize geographic points of interest in the city of Bamberg, Germany, and Fujisawa, Japan, and categorize them semantically. A community of reviewers verifies that the information uploaded by the players (photo, text, GPS coordinates, and location category) is valid (Matyas et al., 2008).	Explore ability to interpret urban environments
<i>COLLAGE</i> (Collaborative Learning Platform Using Game-Like Enhancements)	Players engage in a board-like game on a site of educational interest using mobile phones, PDAs, and GPS capabilities to communicate with one another on site and in the classroom. Educators create mobile learning experiences to support their curriculum with the assistance of an implementation guide and web-based interface for creating and designing the game (Sotirou et al., 2008).	Explore context-dependent and location-based learning
<i>EcoMOBILE</i>	Visiting a pond, players work in pairs to make observations about organisms and classify them (producer, consumer, and decomposer). Players then collect water measurements using the TI NSpire® and environmental probes. They also participate in other activities, to include comparing observations and water measurements with other players. An AR program offers players instructions while at the pond. Later in the classroom, players compile all data and discuss results (Kamarainen et al., 2013).	Explore learning about physical ecosystems and water quality measurements
<i>Environmental Detectives</i>	Players take the role of environmental scientists tasked with investigating health concerns at a site linked to the release of toxins in the local water supply. Players experience a “virtual practicum” similar to working on an environmental research team (Klopper et al., 2002).	Explore effective investigation using quantitative and qualitative data
<i>Explore!</i> (Excursion game)	Players visit the archaeological site of Egnathia, an ancient city in the Apulia region of Italy, where they are given a case to solve. Role-playing as a Roman family, players work as a group using a mobile phone and a map of the site to find their way around, placing markers to solve the case (Ardito, Buono, Costabile, Lanzilotti, & Pederson, 2007; Costabile et al., 2008).	Explore learning about history
<i>Feeding Yoshi</i>	Players explore a city looking for virtual fruit in which to feed their character. Played in teams, players use HP iPAQ 2750s® and 4150s® to collect points by feeding the creatures. The game uses existing public and private wireless hotspots (Bell et al., 2006).	Explore ability to interpret urban environments
<i>Frequency 1550</i>	Players visit the historical city of Amsterdam. Using smart and GPS-enabled video phones and the Internet, players gain citizenship to the city by conducting exercises tied to the themes of labor, trade, religion, rules and government, local knowledge, and defense (Huizenga et al., 2009).	Explore learning about history; player engagement and motivation

Table 1. Continued

Title	Description	Purpose
<i>Massey Mobile Helper</i>	Players are given applicable contextual information (e.g., location of lecture halls and laboratory rooms, and lecture cancellations) in support of their daily school life as they traverse the Massey University campus. Using a PDA phone (HP-IPAQ 6700®) with a Bluetooth GPS device (GlobalSat BT-338®), the game locates players' positions on the university map to provide relevant content (Brown, Ryu, & Parsons, 2006).	Explore acclimating to university life
<i>Mentira</i>	Players learn Spanish in the Albuquerque neighborhood of Los Griegos. Using iPod Touches®, players must solve the prohibition-era murder of Dionisio Silva. Players collect clues and try to solve the murder by exploring various neighborhood locations and examine information provided on their mobile devices (Holden & Sykes, 2011).	Explore learning the Spanish language
<i>MobileGame</i>	Players are given tasks that must be completed at certain spots as they are led through various university locations. Tasks are comprised of one or two simple questions displayed on a PDA (Göth et al., 2004; Schwabe & Göth, 2005).	Explore learning through an orientation-based game
<i>MobileMath</i>	Players working in teams of two are sent to a physical location. Using GPS-enabled mobile devices and instructions, players must draw four vertex shapes (squares, rectangles, or parallelograms) to score points. Correct shapes are added to a virtual map coded by team color for all players to see (Wijers, Jonker, & Kerstens, 2008).	Explore learning mathematics
<i>MobiMissions</i>	Players create missions for other players. Players take a series of photographs and enter text to create missions, which are "dropped" from their mobile phones. Missions remain dropped until found and "picked up" by other players (Grant et al., 2007).	Explore collaborative experiences in a physical space
<i>Mogi</i>	Players collect virtual objects throughout the city of Tokyo. Using a GPS-enabled mobile phone, players catch objects, such as fruits or animals. Virtual objects are depicted on the mobile device when players are within 400 meters of an object (Licoppe & Inada, 2006).	Explore ability to rediscover a city
<i>REXplorer</i>	Players visit Regensburg, Germany. Players use a rented GPS-enabled "game device" with camera-based motion estimation to create encounters with historical figures. Players wave the device to "cast a spell" to awaken the spirit of figures associated with existing buildings and settings throughout the city (Ballagas et al., 2007).	Explore tourists' acclimation to surroundings; learning about history and culture
<i>Savannah</i>	Players explore the challenges experienced by lions on the Savannah. Using GPS tethered to iPAQ 5450® PDAs with headphones, players must balance costs and benefits as well as collaborate and negotiate with one another to meet game objectives (Facer et al., 2004).	Explore conceptual understanding of animal behavior
<i>SciMyst</i>	Players solve different "enigmas" or questions based on real-world information. Using Nokia N80® mobile phones, players either collaborate or play individually to answer questions (Sedano et al., 2007).	Explore collaboration
<i>Sick at South Shore Beach</i>	Players are presented with an environmental scenario and visit South Shore Beach, a mixed-recreational park in Milwaukee, to investigate a collection of illnesses that are linked to the beach. Players are presented with information about the scenario using AR. Using a GPS-enabled PDA, players use the information gathered (along with classroom research) to formulate, present, and defend their final hypothesis about the illnesses (Mathews, Holden, Jan, & Martin, 2008).	Exploring learning about disease related to bacteria found on sandy beaches
<i>Skattjakt</i>	Players collaborate to solve a mystery about a castle located on the Vaxjo University campus. The playing field is spread over six locations throughout the campus. Players find markers using text and audio clues provided on Nokia N70® mobile phones (Spikol & Milrad, 2009).	Explore learning about history; informal skills in map reading

Table 1. Continued

Title	Description	Purpose
<i>SupaFly</i>	Players create and interact through characters in a community-based soap opera. Interaction and character development take place using mobile phones through short message service (SMS) and a website (Jegers & Wiberg, 2006).	Explore social aspects of mobile game play
<i>TimeWarp</i>	Players visit Cologne, Germany. Based on the legend of the Heinzelmännchen, players explore the city to bring back the fabled elves. Equipped with a mobile AR system and a GPS-enabled handheld information device with Bluetooth, players search for relevant locations to interact with various elements to locate the elves (Herbst, Braun, McCall, & Broll, 2008).	Explore learning about history; ability to interpret urban environments
<i>Virus Game</i>	Players learn about the spread of infection using a classroom-based participatory simulation. Moving around a predetermined physical location, players meet one another face-to-face. A custom-built device worn by each player tracks interactions and determines if the infection spread (Colella, 2000, 2002).	Explore learning about the spread of disease

FUTURE RESEARCH DIRECTIONS

While literature on mGBL is mounting, as with video game research in general, findings to date are far from conclusive (Huizenga et al., 2009). DaCosta and colleagues (2015) concluded that much of the research thus far has focused on the technology. To fully appreciate the educational possibilities mobile computing has to offer, experts must look beyond individual devices and functionality (Naismith et al., 2004). That is, the need exists to more thoroughly examine the cognitive aspects of mGBL (Huizenga et al., 2009) if we are to understand how to best leverage mobile computing in educational contexts. As a result, future research should focus not only on the anytime-, anywhere-, and on-any-device characteristics of mobile technology, but pedagogy as well, to include the proper implementation of learning theories and strategies (DaCosta et al., 2015).

CONCLUSION

The huge spread of mobile computing is undeniable, with the draw of mobile gaming reaching

epic proportions. This popularity, along with the unique characteristics of mobile computing, has ignited mounting interest in the use of these games in educational contexts, to the extent that numerous examples can be found in the literature. Although much of the research to date has focused on the technology itself, recent studies of mGBL are promising. Future research should look beyond individual devices and functionality, and place greater importance on pedagogy, emphasizing the learning that can take place through the use of these games.

KEY TERMS AND DEFINITIONS

Game-Based Learning (GBL): A notion rooted in the belief that games can be leveraged in the learning process.

Mobile Game-Based Learning (mGBL): A notion rooted in the belief that games played on a mobile device (e.g., cell phone, personal digital assistant, smartphone, tablet) can be leveraged in the learning process.

Mobile Games: Digitally based games mostly played on mobile devices (e.g., cell phone, personal digital assistant, smartphone, tablet). DaCosta, Seok, & Kinsell.

Video Games: Digitally based games typically played on PCs or dedicated gaming devices, such as a game consoles (e.g., Xbox®, PlayStation®, Wii®) or handheld game devices (e.g., 3DS®, Vita®). DaCosta, Seok, & Kinsell.

INTRODUCTION

The acronym STEM – Science, Technology, Engineering, and Mathematics has entered the agenda of educational policies. Particularly remarkable is the Horizon Report by Johnson et al. (2013), which identified the most notable and emerging issues, trends and digital technology challenges in STEM education for the coming years.

In today's schools, teaching about STEM may take place in many general education and career and technical education subject areas such as agriculture, science, health, technology and engineering, and family and consumer science. Learning about the attributes of STEM and how they connect can help promote innovation. At the collegiate level, STEM education encourages students to pursue STEM careers in order to meet the growing demand for trained professionals in these areas (Reeve, 2015).

The concept of STEM education is being discussed differently by different nations. Whereas some deem STEM education as the improved teaching of the separate STEM subjects, others believe STEM should be taught through an integrative subjects approach. Many believe it is a combination of both of these approaches. Different countries are exploring STEM due to

political and economic pressures and because some believe it is a means to improve the delivery of such knowledge (Ritz & Fan, 2015).

We acknowledge the strategic role of science and mathematics learning. But how to foster it? “Games” might be a promising answer. Games are successful at making people spend time trying to reach goals via a well structured set of rules - and STEM domains are also bound by well structured rules. Thus, if we could make games that would embed the rules of those domains into their gameplay, well, maybe our students would enjoy learning science and mathematics. Rapini (2012) points out that games are now being revisited as educational tools by several leading organizations, i.e.: MIT's Education Arcade and Games-to-Teach project; Woodrow Wilson Foundations' Serious Games Initiative; University of Wisconsin's Games Learning Society; the Federation of American Scientists; the Bill and Melinda Gates Foundation; and the U.S. Department of Education. Some of them - markedly those from MIT's Education Arcade project - have been developed with mobile devices in mind.

Regarding mobile device widespread use in STEM education, Johnson et al. (2013) indicated the relevance of games and gamification in STEM learning and teaching: a) discovery-based and

goal-oriented learning is inherent in educational games and this strategy offers opportunities for collaboration and development teamwork skills; b) educational games can be used to teach interdisciplinary concepts in many complex scientific issues in a more appealing way than traditional methods; c) simulations and serious games allow students to recreate difficult situations to try new answers or pose creative solutions.

And, lastly, our choice to narrow the focus of this paper down to mobile devices is due to the impressive influence they have over our lives and to the amount of time we spend on them. The revolution of mobile devices + wide internet access is so deep that it is making the very action of “making a phone call” obsolete. We have been using mobile devices for a myriad of tasks - so how can we use them for learning purposes? These are the concerns presented in this paper.

BACKGROUND

The development of mobile game-based learning has been seen as a new line of research and technological development in the field of educational technology, STEM education and game design.

These fields are rather new and intrinsically multidisciplinary, making it even more exciting. Regarding the use of mobile devices for teaching and conceptual learning, we can highlight the work of John Traxler. He is the Director of the Learning Lab at the University of Wolverhampton and a Founding Director of the International Association for Mobile Learning, among many other academic attributions related to m-learning.

Due to their role as pioneers on Multimedia Studies, we cite professor Richard Clark – from the University of Southern California – and professor Richard Mayer – from the University of California – since they are on both sides of the scale: Clark says instructional design is all that matters; Mayer says multimedia design is also a key for effectiveness. Professor Robert Kozma – currently (2016) emeritus director and principal

scientist of the Center for Technology in Learning – could be pointed out as a leading scholar. His numerous publications focus on the potential of IT in learning contexts, as well as Science and Mathematics Education (he is a multidisciplinary researcher).

And lastly, regarding Game Design, we would highly recommend our readers the work of Stefan Björk, Göteborg University, Sweden, who is certainly one of the leading scholars in the field of Game Design. Regarding Games and Affection studies, we would cite Boehner et al (2017) and Quigley (2014), who have been studying how the theoretical foundations of affection interact with the instruments used to measure it.

CURRENT SCIENTIFIC KNOWLEDGE IN SCIENCE AND MATHEMATICS LEARNING GAMES FOR MOBILE PLATFORMS

There is a growing interest in Mobile Game related research, whether strictly technological or applied in social contexts. We thought a nice way to connect this data and depict the current scenario would be to break the subject into pieces: Game Design; Affection and Play; Mobile Learning; Games for Learning; Science and Mathematics Education; and lastly, summarizing it in the Games for STEM Education section.

Game Design

The association is direct: people enjoy playing games, people love their mobile gadgets; if we want people to enjoy better learning performance and experiences, we should have them play mobile games! But before engaging with game development, it is important to not only acknowledge the technological options, but to also be aware of the design process and workflow. The reasoning for this is because it is most certainly teachers who will be asking for the development of a game, and they are likely to also be game designers (because

the development team do not master the subject domain). According to O'Neil et al (2005), Linehan et al (2011), and Brom et al (2011), while it seems apparent that games have the potential to function as valuable teaching tools, there is very little evidence that they 1) produce reliable, valid and long lasting educational outcomes, or 2) do so better than traditional education structures. Linehan et al (2011) highlight the importance of content, but you should not focus too heavily on it to the detriment of gameplay; it must be intrinsic to gameplay. A fictitious example of bad anchoring to content would be a game where you have to save a princess by answering correctly to algebraic problems. For these reasons, it might be worth understanding how games may be designed.

With many different types of games, target audiences and content demands, there is not a large number of scientific studies on this subject. Even when it comes to books on the game design process, plenty of different approaches can be found depending on game type and platform (mobile, digital and board games). As references of such variety, we cite Barwood's (2001) game design guidelines, patterns for game design (Kreimeier, 2002; Björk & Holopainen, 2005) and tools for supporting specific game design tasks (Cook, 2012; Hunicke et al. 2004; Brathwaite & Schreiber, 2008; Davidsson et al., 2004). Furthermore, we think we should mention two well known game design methods: Schell (2008) and Fullerton (2014). Both authors propose an iterative method based on play testing with prototypes of varying degrees of functionality. None of those references is specific for educational games or even mobile games, but they are all very enlightening, even for persons who have some experience.

Out of these, we would like to highlight the design approaches to game design found in Hunicke et al. (2004) and Björk & Holopainen (2005). The book *Patterns in Game Design* (Björk & Holopainen, 2005) is a comprehensive collection of more than 200 design patterns – descriptions of recurring interaction elements of gameplay that are shared by several games.

Each pattern has a name and a description, and also include the relation with other patterns and consequences/examples of use. It is a great way to become familiarized with game vocabulary and to recognize game design strategies that might be subconscious even to experienced game players. Hunicke et al. (2004) has a similar but broader approach, since it does not point to gameplay elements. They divide every game into three zones: rules, systems and fun, which, in turn, are linked to design counterparts: mechanics, gameplay and aesthetics. Mechanics create gameplays that produce aesthetic experiences.

Next we review studies focusing on the assessment of affective states while playing educational games. We consider this an important subject because affection might be the most prominent difference between games and all other pedagogical strategies (digital or not).

Affection and Play

A number of studies focus on the relation between affective states and gameplaying. In this section, we review some of those studies. With affection being a very broad subject that encompasses several areas (mainly psychology, neuroscience and artificial intelligence), we narrowed our search down to educational game evaluation. Those studies are mainly from the area of Human Computer Interaction, an applied science area. The authors of such papers usually restrict their experimental designs to one or two affective states, as it is difficult to identify and distinguish between such states. For a thorough analysis of theoretical views on affection, we recommend the review by Boehner et al. (2007) and Quigley (2014).

The studies we have reviewed relate to motivation and flow, and how these relate to game design. For example, Kapp (2012) and Clark & Rossiter (2008) investigated the relation between corrective feedback and motivation, while Brookes e Moseley (2012) and Wood et al. (2014) investigated how the possibility of failing and starting again can enhance motivation. We believe these

design elements are important because they favor hypothesis testing in the game.

Increasing motivation is also related to the perceived challenge posed by the game (Hanus & Fox, 2015; Sharek & Wiebe, 2014; Admiral et al, 2011). If it is challenging and the player succeeds, they can feel very proud of their achievements, otherwise, there might be feelings of helplessness and incompetence (Mc Gonigal, 2011), which, of course, game designers try to avoid. A well balanced challenge can lead to engagement, an affective state similar to flow but with less pronounced effects (in Jennett et al, 2008 the reader will find a comprehensive distinction between those states). Level design might be an important key to balancing challenge (Sharek & Wiebe, 2014; O'Brien & Toms, 2010; Pavlas et al, 2010). The flow state is deep involvement with the game, high concentration, and gradual loss of time awareness (O'Brien & Toms, 2010; Pavlas et al, 2010; Sharek & Wiebe, 2014; Shute et al, 2014). Breaking flow states leads to great frustration. Hsieh et al (2016) analyzed the relation between flow experiences and performance on students of elementary schooling level and saw that both variables work together.

Mobile Learning

The expression *mobile learning* may be associated with several meanings depending on the context it is inserted within, user objectives, geographical location, and even the era of reference. Traxler (2009) reports on how the different facets hinder an outline of a description as to what mobile learning would be. Following a global analysis that considered all the continents, the definition by Taylor (2006) stands out, according to which *mobile learning*, or as he deems more appropriate, *learning in the mobile age*, means learning through handheld equipment, or; learner mobility carrying their mobile devices, or; mobility of knowledge and/or resources accessible anywhere.

In that same sense, Sawaya & Putnam (2015) and Crompton (2013) adopt the *m-learning*

concept as “learning within multiple contexts, through social and content interactions making use of mobile, personal electronic equipment”. Therefore, they consider the use of handheld equipment (tablets and smartphones) in education in both senses. Hung & Zhang (2012) foresee a huge growth in the amount of publications in this field and provided a list of countries that are source of research on Mobile Learning (n = 119 papers) – Taiwan (27%), United States (15%), and South Korea (9%). Hwang & Tsai (2011) also analyzed this variable and found similar results: Taiwan (42%), United States (10%), and United Kingdom (13%).

There is some very remarkable data in the reviews by Wu et al (2012), Hwang & Tsai (2011) and Connolly et al (2012): the distribution of subjects that are the most frequent themes. We point out the relatively small number of Science and Mathematics related game studies, excluding Computer Science, which would naturally have more studies. For us it was a surprise to find such a high amount of studies related to Language and Linguistics.

Games for Learning

James Paul Gee (2003, 2008), a prominent advocate of Games for Learning, listed several properties of games that make them special tools for learning, e.g.: “the use of affordance matches between bodies or tools and worlds” and “using models to make learning from concrete experience more general and abstract”. Gee (2008, 2009) considers successful video games as highly engaging problem-solving spaces. Since they are often long, difficult and complex, they must be learned and mastered in effective ways. Gee & Morgridge (2007, p.1028) believe that video games make players think like scientists, with gameplay being built on a cycle typical of experimental science: “hypothesize, probe the world, get a reaction, reflect on the results, re-probe for better results”.

Regarding Games for Learning, we found two recent reviews and one somewhat older review.

One of the more recent reviews carried out by Connolly et al (2012) had each paper assigned a “quality score” – the lowest score possible was 5 and the highest 15. The mean rating of 8.56, and 70 papers (54% out of 129) were above average. Out of these high quality papers, 52% were about “entertainment”, 37% were “games for learning”, and 11% were “serious games”. Regarding game genre, from the 34 high quality papers about “Games for Learning” or “Serious Games”, 6% (2) were Action games; 73% (25) were Simulations; none were Mobile games.

The review by O’Neil et al (2005), albeit older, has been referred to by several previous studies. They analyzed 19 papers from 1990 to 2005 to support the hypothesis that positive findings might be attributed to instructional design, not to games per se (p.462). This hypothesis is in consonance with Clark’s “method-not-medium” hypothesis, which seems to have very low popularity nowadays, despite the strength of Clark’s arguments. Regarding this subject, the reader might want to follow Richard Clark and Robert Kozma’s debate. Robert Kozma is an eminent advocate of multimedia potentiality, especially for Science Learning. Some of the most interesting papers are Clark (1994); Kozma (1994); Clark & Feldon (2005).

Li & Tsai’s (2013) literature review found a gap between students’ possible learning experience with games and their learning outcomes being assessed: the games did not fully take advantage of the potential of genres and platforms. The authors cite examples of MMO (Massive Multiplayer On-line) games in which the students explored the world and solved tasks individually. Moreover, even when game designs were guided by different theories or models to provide a variety of learning opportunities, learning was still mainly focused on scientific and mathematical knowledge or concepts. We agree with Li & Tsai (2013) when they say the affordance of game environments to facilitate science learning has not yet been fully explored and requires further investigation.

Science and Mathematics Education

Nowadays (in 2016), it could be said that, within the Science and Mathematics teaching and learning context, we are experiencing a paradigm shift regarding the use of mobile technologies in school activities.

Borba et al. (2014) listed the four phases in the use of digital technologies in Mathematics Education, and the respective tools that may represent them: 1st phase – computer programming, constructionism and Seymour Papert’s LOGO language; 2nd phase – dynamic geometry software such as Cabri Géomètre and GeoGebra; 3rd phase – Internet and distance education; and the current 4th phase – fast Internet and mobile technologies. The 4th phase seems to retrieve aspects from the previous phases that may be better explored due to the technologies that were non-existent in their original context.

Borba & Villarreal (2005) state that knowledge is being produced collectively by human beings and technologies and coined the expression *humans-with-media* in opposition to the idea that pieces of knowledge are only built by persons, either in groups or individually.

Bekebrede et al. (2011) defined this generation of students as the *gamer generation* or *net generation*, who have their lifestyles and social interactions harnessed to the digital technologies they have lived with since childhood. Those students express a preference for active, collaborative, technology-rich learning, which is motivation to include digital games in teaching practices.

With emphasis on the teaching of Mathematics, Misfeldt & Gjedde (2015) consider three ratings for educational games: i) as a means to present some piece of knowledge that stands out in relation to other traditionally adopted means; ii) as an instrument that controls or directs a more complex activity; or iii) simply as an object that may be developed and analyzed by teachers and students.

Games for STEM Education

Masek et al (2012) indicate that digital games allow the handling of multiple representations associated with scientific knowledge. In this way, multimodal representations can be used to scaffold the construction of understanding, scientific explanations and reasoning. Girard et al (2013) suggest that the use of games also allows for the harmless simulation of many physical situations and natural phenomena that cannot be reproduced in real-world situations (such as ecological disasters, astronomical phenomena and emergencies). The Graz University of Technology produces several types of Mathematical applications for iPhones and iPads. Based on those products, Ebner (2015) lists four categories:

1. **Stand-Alone Learning Apps:** Applications that do not require registry or Web connection, allowing to be accessed anywhere. Pedagogically, they do not require outside instructions or other persons to be played, which hinders any learning assessment.
2. **Game-Based Learning Apps:** Feature some problem solving characteristics, such as variable answers and problematization of a contextualized situation, with added competitiveness. The increase in gamification has mitigated high programming costs.
3. **Collaborative Apps:** Seek to stimulate group activity and collaborative learning social interactions in addition to exploring the differentials of mobile devices through Bluetooth communication or WiFi connection.
4. **Learning Analytics Apps:** This category aims to aid teachers in verifying student performance by accessing individual data in each device, allowing for further statistical analysis.

For meaningful learning of STEM concepts to take place, it is important that teachers and app developers take into account three pedagogical

issues: the possibilities the mobile device allows; learning objectives; and types of activities that may be elaborated (Sawaya & Putnam, 2015).

1. **Possibilities:** Insert data and perform computing procedures such as complex calculations; - Access information on websites, audios videos, etc.; capture images, videos, audios and localization via GPS; communicate and share information and files for joint work; and create materials that may be promptly used by colleagues and teachers.
2. **Learning Objectives:** Construct new items of knowledge through problem solving within mathematics or contextualization; relate and apply mathematics in other areas of knowledge; make use of representations to model and interpret physical, social and mathematical phenomena.
3. **Types of Activities:** Presentation of new content; mathematical comprehension exercise tool; investigation activities; applications in different contexts; creation of diversified materials.

It is important to highlight that all above listed features already exist in schools. The advantage of mobile devices is the capability of aggregating and optimizing all possibilities in a single electronic apparatus. With emphasis on geometry teaching, location-based game MobileMath (Wijers et al., 2008; Wijers et al., 2010) is an ideal example of a mobile learning game that includes such requirements.

FUTURE RESEARCH DIRECTIONS

To open this section, we would like to rely on our experience as designers of Games for STEM Education (Eichler et al, 2003; Eichler et al, 2005; Eichler et al, 2011; Perry e Eichler, 2015; Perry et al., 2012; Perry & Schnaid, 2012) to point out possible causes for the gap Li & Tsai (2013) found between students' possible

learning experience with games and their actual assessed learning outcomes. We hypothesize that it is due to the nature of game development. Games are the most difficult kind of software to both design and develop – code and design requirements are usually unique, not shared among projects, and usually complex (Blow, 2004). The more sophisticated a game is, the more difficult (and expensive) it becomes to find skilled personnel. We see some possible ways to overcome this situation:

1. When the game is to be developed by educational institutions, money and time are the critical resources, in that order. Financial resources could be allocated for hiring professional game designers and developers. Subject domain knowledge, as a resource, is available in educational institutions, with educators having classroom experience, knowing what topics alumni find more difficult and the pedagogical strategies to approach those topics.
2. When the game is to be developed by educational institutions, financial and time resources could be allocated for personnel training — educators, researchers, technical staff and students. The use of financial resources would decrease vastly, but it would take some time to create a cohesive and mature team. Additionally, design and development could be restrained by the skill set of the team. This could be an interesting institutional approach, since equilibrium would be reached at some point, after which the ROI (Return On Investment) would be positive.
3. When the game is to be developed by studios, then the critical resource is knowledge of the subject domain. Studios could associate with educators to bridge this gap. In this case, it is important to give educators time to become familiar with the game development process.

In our experience, we have perceived that mobile technologies are already present in schools, but still face obstacles for their acceptance in the classroom. That is why prohibitive norms should be reviewed and activities carried out to motivate teachers to accept incorporating such resources in their school practices.

Traxler & Crompton (2015) highlight that Bring Your Own Device (BYOD) may be a good option for Web access at schools be broadened out to every environment and to all students. As part of this project, each one may use their own personal equipment in professional and schooling environments, leveraging the speed of wireless Internet. In addition to digital inclusion, this action would reduce equipment acquisition and maintenance costs and eliminate the need for an underused computing laboratory.

Following this idea, Borba & Lacerda (2015) suggest the One Cellular Phone per Student Program for Brazilian schools, being motivated by the modest advances observed in previous national projects, also taking into account the *humans-with-media* present in schools and the need to encourage continued training for the faculty who are in classrooms already and those in early training.

Lastly, we suggested in Perry & Eichler (2015) that one path to be taken for further qualification in digital educational games would be to encourage their development by teaching institutions, though that is still at an early stage and lacking an attractive visual design.

CONCLUSION

In the face of the above exposed, our conclusions point to the fact that we are taking the first steps in a digital game development process for teaching mathematics in the school environment and the acceptance of Smartphones as tools that add value to education. By uniting both trends, it is possible to direct game design to promote collaborative activities and go beyond the classroom.

KEY TERMS AND DEFINITIONS

Game Design: Refers to the art of applying design and aesthetics to create a game to facilitate interaction between players (our learners) for either entertainment or educational purposes. This is not a scientific area of research, so the reader will find most of the information in books and on web portals such as GamaSutra. The information can be Design or Technology oriented (it will be easy to distinguish, even for the uninitiated reader).

Games and Affection: Refers to the study of measuring affective states while playing. The greatest challenge is to distinguish between states, to design instruments that can capture such states and to create experimental settings in which the player is affected solely by the game. Very tricky an interdisciplinary scientific area.

Games and Learning: Refers to a field of education research that studies what is learned by playing games, and how design principles, data and communities of game play can be used to develop new learning environments. An interdisciplinary scientific area which has grown since the early 2000s.

Mobile Learning: Refers to a way of learning across multiple contexts, through social and content interactions, using personal electronic devices. An interdisciplinary scientific area which has grown since the early 2000s.

STEM Education: Refers to the academic disciplines of science, technology, engineering and mathematics, the acronym is typically used when addressing education policy and curriculum choices in schools to improve science and technology development. A very strong and established scientific area since 1950.

Mobile Learning in and out of the K–12 Classroom

Pena L. Bedesem

Kent State University, USA

Tracy Arner

Kent State University, USA

INTRODUCTION

Today there is widespread ownership of mobile technology, including mobile phones, tablets, chromebooks among school-aged youth. To wit, researchers report that nearly 70 percent of 8- to 18-year-olds own their own mobile device. In parallel with increased accessibility and usage, researchers in various fields of education have begun to explore how mobile technology can impact teaching and learning. In this chapter, we discuss the work of pioneering scholars in the area of emerging technology in K-12 education. Next, we describe the current scientific knowledge on the ways in which mobile technologies are used by students in K-12 education. We then review important research that highlights the added effects of mobile technology to support non-traditional learners. Recommendations for future lines of investigation and further reading are provided.

BACKGROUND

The processes involved in student learning are now as never before. Delivery of information is more various, instantaneous, and itinerant and thus new ways of information delivery and instructional models are necessary to meet the needs of 21st Century learners. One method of meeting these needs is by using *mobile technologies*. Mobile technologies are digital devices that include tablets, personal digital devices, Chromebooks, and

mobile phones. The use of these technologies in the classroom is commonly referred to as *mobile learning*. This chapter will focus on the use of mobile technology to engage students, enhance instruction, and support non-traditional students including those with disabilities and students who are non-native English speakers.

In today's society mobile devices have become a ubiquitous technology. For example, 88% of adults (Zickuhr, 2011) and 77% of teens (Lenhart, 2012) own a mobile phone. The most recent Speak Up Survey by Project Tomorrow found that over 80% of secondary students have their own device to use for learning. Further, more and more schools are purchasing tablets, Chromebooks, and mobile media players to augment classroom instruction (Herold, 2016). In spite of the increasing availability of mobile technology in learning environments, deliberate integration into daily instruction, by teachers, is not as prevalent. Teachers cite numerous concerns with the use of technology including readiness, lack of training, classroom disruption, cheating, and access to inappropriate content as barriers to consistent integration into instruction (Kim, Kim, Lee, Spector, & DeMeester, 2012; O'Bannon & Thomas, 2014; Thomas & O'Bannon, 2013; Thomas, O'Bannon, & Bolton, 2013). Despite these barriers, the constantly increasing functionality and decreasing cost of mobile devices is making them both accessible and valuable learning tools both in and out of the classroom (Thomas, O'Bannon, & Bolton, 2013). Moreover,

DOI: 10.4018/978-1-5225-2255-3.ch555

researchers have shown increases in student motivation (Brown, 2008), and active participation (Kinsella, 2009) when technology is used in the classroom. Given the promise of mobile devices as instructional tools in K-12 education, it is important to discuss (a) pioneering work that has led to the use of mobile technologies, (b) stakeholder perceptions of using technology in the classroom, (c) how mobile technologies are being used, and (d) future research directions.

PIONEERING SCHOLARS

Marc Prensky, Mark van 't Hooft, and Liz Kolb were among the first educational researchers to advocate for the use of technology to meet the needs of the new learner in K-12 classrooms. While these researchers focus on different aspects of technology integration, collectively they account for important conceptual and empirical contributions that led to the acceptance of mobile devices as instructional tools. Instructional uses may include Internet research, communication, note taking, reading, organization, video-based instruction and more (Sansosti & Bedesem, 2015).

Marc Prensky is credited for coining the terms *digital natives* and *digital immigrants*. According to Prensky (2001), digital natives are of the generation born after 1980, whereas digital immigrants are of the generation born before 1980. Digital immigrants have to learn to adapt their environment and work at integrating technology into their daily lives. On the other hand, digital natives are characterized as immersed in technology including computers, videogames, digital music players, and mobile phones, and can seamlessly integrate technology into every aspect of their lives. Prensky posits that as a result of being exposed to a technologically rich environment and the sheer volume of students' interaction with it, today's students think and process information fundamentally different from digital immigrants. Thus, to stay engaged during learning activities

digital natives have come to expect the same level of technology integration in the classroom as in their personal lives (Martin, & Ertzberger, 2013).

Mark van 't Hooft has been active in the area of mobile learning since 2001, beginning with the Palm Education Pioneer (PEP) Project - the first large-scale evaluation of handheld mobile technology for education. Through the PEP Project, 175 K-12 classrooms throughout the United States were provided sets of handheld computers. An overwhelming majority (90%) of teachers who participated in the PEP Project indicated handheld computers are effective instructional tools that have the potential to have a positive impact on students' learning, and that they would continue to use handhelds in the future. In a later study, Swan, van 't Hooft, and Kratcoski (2005) examined students' use of mobile technologies and the effects on their motivation to learn and engagement in learning activities, as well as their teachers' support for the learning process. Their findings suggest that use of the mobile technologies resulted in increased student motivation, engagement, productivity, and quality of work. Teacher interviews also indicated using mobile technologies enhanced the learning process, especially in the area of writing. Moreover, several teachers noted improvements in the writing of students with disabilities and commented on the benefit of mobile technologies for lessening the performance gap between students with and without disabilities.

Liz Kolb's work explores methods teachers and students can use to integrate "everyday technologies" to which students have become accustomed, into the classroom. Specifically, Kolb investigates the integration of mobile phones into classroom instruction as a way to better connect how students use technology in everyday communication and the way they use technology in the classroom (Kolb, 2008). Mobile phones can be used, for example, to increase engagement, enhance instruction, and extend learning beyond the typical school day. In this area, Kolb has published two

books on how teachers can use mobile phones in the classroom for authentic purposes. Her first book, *Toys to Tools: Using Student Cell Phones in Education* (2008), explored ideas for authentic lessons, solutions for common concerns, and research to support the use of mobile phones in education. The purpose of her second book, *Cell Phones in the Classroom: A Practical Guide for Educators* (2011), is to “illustrate many practical ways to use cell phones in learning: classroom groups, individual projects, homework outside of the classroom, field trips, and as communication tools for teachers, students, and parents” (p. 1). In this book, Kolb presents 16 case studies to demonstrate how teachers use mobile phones in education and illuminates their experiences and activities. In addition to her books, Kolb also maintains a website (www.cellphonesinlearning.blogspot.com) with a host of resources including lesson plans that use student mobile phones and information about mobile safety education.

The work of Prensky, van ’t Hooft, and Kolb has significantly influenced research in the area of technology and its application in educational settings. Together, they have identified the new learner, examined the use of emerging technologies as instructional tools, and provided practical classroom applications for educators. They have also encouraged schools to keep up with the advances in technology and adopt programs such as Bring Your Own Device (BYOD) to reduce the cost of providing and maintaining equipment. Additionally, their work has led to research in how educators can use mobile phones in K-12 education to support all students, including those with disabilities.

CURRENT SCIENTIFIC KNOWLEDGE IN K-12 Education

In the following sections we discuss the perceptions of the use of technology in education, including the perceived benefits of and barriers to their

use. Next, we highlight how mobile technology is currently being used in the classroom. Finally, we make recommendations for future research and further reading.

Stakeholder Perceptions of Technology Integration

The increase in availability of mobile technology in the hands of students has led to an increase in classroom integration. The degree and method of integration vary considerably across teacher experience levels. Digital Natives, as defined by Prensky (2001), are now becoming pre-service teachers (Lei, 2009). In spite of the normality of technology in their daily lives, these pre-service teachers may not be prepared to be digital teachers. They exhibited strong positive feelings about technology in education but were not confident in their ability to use more complex technology in the classroom (Lei, 2009). In 2014, O’Bannon and Thomas focused on age as it relates to support for the use of mobile phones in the classroom. They found that teachers who were in age ranges 33-49 and teachers 32 and under were significantly more supportive of mobile phones in the classroom than teachers 50 and older. The depth and frequency of technology integration is also tied to teachers’ Technological Pedagogical and Content Knowledge (TPACK) and beliefs in the integration of technology (Kim et al., 2012).

Perceived Benefits of Mobile Technology

Researchers have also examined the perceived benefits of using mobile technology in the classroom. Teachers (pre-service and in-service), parents, and school administrators believe that some benefits of using technology in classrooms are increased student engagement and motivation as well as developing proficiency in 21st Century Skills such as communication and collaboration (Project Tomorrow, 2015; Thomas & O’Bannon,

2013; Thomas, O'Bannon, & Bolton, 2013). Three quarters of the 431,000 students surveyed by Project Tomorrow (2015) believe that using a tablet, phone, laptop or Chromebook is essential to their educational experience. Students indicate significant educational use both inside and outside the classroom walls with activities like emailing teachers with questions, watching instructional videos, and contributing to class blogs (Project Tomorrow, 2015). Teachers and administrators described an increase in the use of blended learning environments, accessed on a variety of mobile devices, as beneficial to student learning outcomes (Project Tomorrow, 2015). Pre-service teachers also have strong, positive beliefs regarding classroom mobile technology use citing an increase in access to information, extending learning beyond the classroom walls, increased student to teacher communication (Lei, 2009; Thomas & O'Bannon, 2013).

Perceived Barriers to Mobile Technology

Pre-service and in-service teachers have identified a variety of possible barriers to substantial integration of mobile technology. Kim et al., (2012) separate barriers into two categories; first order and second order. First order barriers consist of issues such as computer access, Internet, or teachers' technological pedagogical content knowledge. Second order barriers are related to teachers conceptual and epistemological beliefs. Classroom integration of technology is highly correlated with teachers epistemological beliefs specifically in lesson design, implementation and class discussion (Kim et al., 2012).

Teachers across studies identified classroom disruption, cheating, and access to inappropriate content as barriers to the use of technology in the classroom (O'Bannon & Thomas, 2014; Thomas & O'Bannon, 2013; Thomas, O'Bannon, & Bolton, 2013). In-service teachers also identified cyberbullying, sexting, and the negative impact of texting on student writing as additional

barriers (O'Bannon & Thomas, 2014; Thomas, O'Bannon, & Bolton, 2013). O'Bannon and Thomas (2014) also found that teachers over 50 years old perceived each barrier as being more problematic than teachers 33-49 and teachers 32 and under. According to Thomas and O'Bannon (2013), pre-service teachers were less concerned about access to inappropriate content, sexting, or cyberbullying than they were about classroom disruption and cheating. Lei (2009) found that in spite of the widespread access to and use of technology in the daily lives of pre-service teachers, they were apprehensive about how to successfully integrate mobile technology into instruction. Ally and Prieto-Blazquez (2014) suggest that teacher training programs be redesigned to prepare teachers to enter the technology-enhanced classroom. Teachers also indicated concern about future students becoming too dependent on technology and believe that some content is better taught without technology (Lei, 2009).

How Mobile Devices are Used in K-12 Education

A review of the literature revealed little empirical research on the use of mobile devices in K-12 education. Much of the research on the use of technology in education focuses on higher education and professional education settings. Institutions of higher education are implementing mobile technology to increase access and flexibility for students (Ally & Prieto-Blazquez, 2014). For example, researchers have examined the use of text messaging to support students' transition to the university setting (Harley, Winn, Pemberton, & Wilcox, 2007), the use of mobile phones as audience response systems (Tremblay, 2010), anonymous peer feedback (Rotsaert, Raes & Schellens, 2015) and perceptions of faculty and graduate students regarding mobile phone use in college classes (Burns & Lohenry, 2010).

Empirical research in K-12 education is gradually increasing as access to mobile devices and Internet connectivity become more common.

Current research shows that mobile technology holds great promise for educational use. One instructional use that has an increasing body of research is the adoption of simulations to provide authentic learning environments for students in science classrooms. A simulation is a computerized reproduction of a process or model of a system in which the user can manipulate inputs or steps in the process to analyze the varying outcomes (Rutten, van Joolingen, & van der Veen, 2012). Simulations may be used to enhance or replace traditional instruction or to enhance or replace laboratory experiments. In a review of literature on simulation use in the science classroom, Rutten et al., (2012) found that nearly all studies provided evidence of increased student comprehension and conceptual understanding.

Thomas and Orthober (2011) examined the use of text messaging in secondary classrooms. In their study, high school students in three different classes received school-related text messages from their teachers once daily. One teacher sent only reminders about assignments and the other teacher used text messages to communicate on a variety of school-related topics. The authors reported that an overwhelming majority of students (92%) found school-related text messages from their teachers helpful and 11% of the students used text messaging to ask their teacher questions and for help on homework. The instructors also expressed that they thought the text messages were helpful for students and noted that the students were better prepared for class. Results of this study demonstrate that mobile phones and text messaging have the potential to positively impact student learning and engagement.

Researchers have also begun to look at the use of mobile technology to support English Language Learners in elementary and middle school (Liu, Navarrete & Wivagg, 2014). Students and teachers were provided an iPod Touch to support teaching and learning over the course of one school year. Student devices were setup with applications and multimedia to support language acquisition such as creation of vocabulary study guides with the

Storykit application. Teachers reported that they were better able to differentiate instruction for the various levels of language acquisition. Students indicated the benefit of increased practice time and extended learning opportunities due to the 24/7 access to the device as well as increasing family engagement in the educational process (Liu et al., 2014).

Additionally, researchers have begun to examine how mobile phones can be used as *assistive technology* to support students with disabilities. Assistive technology is defined as any item, piece of equipment, or product system that is used to increase, maintain, or improve functional capabilities of individuals with disabilities (Individuals With Disabilities Education Improvement Act, 2004, I.A.602.1). Although the language used here to define assistive technology is broad, the majority of assistive technology in schools is typically packaged technology programs such as text-to-speech programs, word-prediction programs, and screen magnifiers (Edyburn, 2004). These packaged programs assist students with disabilities by compensating for a student's disability; however, they are costly, stigmatizing, and disconnected from the student's use of everyday technology (Bouck, Shurr, Tom, Jasper, Bassette, Miller, & Flanagan, 2012).

As mobile technology becomes more ubiquitous, manufacturers are increasing the number of assistive technologies that are native on mobile devices. Apple has incorporated intuitive tools to assist with vision impairment, hearing impairment, motor skills deficits, and learning and literacy impairments. Native accessibility tools include Dictation, Voice Command, VoiceOver, Speak Screen, Zoom, and Siri, a personal digital assistant that will respond to voice commands from the user (Apple, 2016). Google has also provided increased access for mobile technology users with tools like "Ok, Google" which will perform Internet searches via voice request from any mobile device and perform over 70 additional voice requests on devices with the Android operating system (Knoll, 2016).

Augmented Reality (AR) technology allows users to combine real and virtual objects through overlays of text, images, video, 3D models, or sounds (Bower, Howe, McCreddie, Robinson, & Grover, 2014). Educational applications of AR are emerging which allow educators to incorporate marker-based learning experiences around a specific content area such as space, microbiology, and language learning. Additionally, technologies are now available that allow teachers to create their own Augmented Reality, marker-based learning units. Students access the content using an app on their mobile device (Bower et al., 2014). Teachers are able to add game-based elements, digital storytelling, and physical activity to instructional units through the use of AR and GPS coordinates (Dunleavy, Dede & Mitchell, 2009). Students report an increase in motivation and improved attitudes about learning. Some research indicates improved learning outcomes as well (Bower et al., 2014).

Escobedo et al. (2012) used mobile phones equipped with an AR application to facilitate social skills practice in real life situations with students with autism. The authors developed an application that guided students with autism through six fundamental social skills of the Social Compass Curriculum (e.g., make eye contact, maintain appropriate personal boundaries, reply to conversation initiators, share interests with partners, disengage appropriately at the end of an interaction, identify potential communication partners). Escobedo and colleagues reported that the use of the mobile phones with the application positively impacted social interactions and increased the number of social interaction by 56.73%. Additionally, the authors noted that students learned how to use the mobile phone and application with minimal assistance, were excited to use it, and found it helpful.

Bedesem (2012) examined the use of mobile phones to change and support behavior in educational settings. Bedesem taught middle school students with mild to moderate disabilities (e.g., ADHD, LD) how to self-monitor their on-task behavior in an inclusive general education classroom.

For her study, Bedesem developed an intervention, called CellF-Monitoring that combined mobile phones with social networking to aid students in staying on task during instructional time. The author reported that the procedure produced positive changes in the on-task behavior of student participants. Additional findings indicate that the mobile phones did not seem to distract the students or their peers and that the teachers and students expressed an overall satisfaction with the CellF-Monitoring procedure.

FUTURE RESEARCH DIRECTIONS

Technology use in K-12 education is still an emerging literature base. There are articles, blogs, books, and websites dedicated to how educators can incorporate technology into instruction, assessment, feedback, and communication but empirical research on the subject is scarce. More research is needed on how the use of mobile technologies affect student engagement, motivation, differentiation and learning outcomes. Additionally, further exploration is needed on how schools can minimize barriers to the integration of technology as a regularly used tool for learning. Student access to technology has increased greatly through personally owned devices as well as technology provided by schools. Access to technology for learning is not available for all students and varies greatly between, public and private institutions as well as those separated demographically and geographically.

With respect to students with disabilities, technology holds great promise for increasing independence, learning and practicing social skills, and changing and supporting behavior. More evidence, however, is needed on the prevalence of mobile use among students with disabilities for instructional use as well as improving quality of life. Studies that report ownership and usage of technology among students do not report rates specific to students with disabilities. Prevalence rates specific to students with disabilities would

determine if technology ownership among students with disabilities is the same as their non-disabled peers. This is important because the rationale of using technology in the classroom that is often cited in the literature is the ubiquitous nature of the devices. However, if fewer students with disabilities have access to technology, compared to their non-disabled peers, then the current progress toward increasing technology integration in the classroom is widening the digital divide between students with and without disabilities.

CONCLUSION

Additional research is needed in the area of preparing pre-service teachers to enter the classroom as digital natives. In spite of frequent personal technology use, teacher candidates are not adequately prepared for seamless integration of technology when they enter the classroom. Pre-service teachers are comfortable with digital consumption but become less confident when working with more sophisticated technology for instructional use. Pre-service teacher programs need to include technology training integrated with the curriculum, pedagogy, and intervention training for the training to be effective. Technology only courses may not provide concrete instances of instructional use that pre-service teachers can adopt upon entering the classroom (Sansosti & Bedesem, 2015).

KEY TERMS AND DEFINITIONS

Assistive Technology: Any type of equipment that can be used to increase, maintain, or improve functional capabilities of student with disabilities.

Augmented Reality: The blending of physical and digital worlds, often with a virtual overlay on a physical item.

Mobile Phones: A telephone that uses cellular towers so that it can be used anywhere.

Mobile Technology: Any portable electronic device that accepts, processes, and stores data at high speeds (e.g., smart phone, tablet computer).

Simulation: A technologically based reproduction of a real world event in which variables can be manipulated by the user.

Students with Disabilities: Students with disabilities are students who have been identified, assessed, and determined to be eligible for special education services under the Individuals with Disabilities Education Act.

M

A Psychological Perspective on Mobile Learning

Melody M. Terras

University of the West of Scotland, UK

Judith Ramsay

Manchester Metropolitan University, UK

INTRODUCTION

The mobile internet offers 24/7 access to a wide range of social, commercial and educational opportunities. If the educational opportunities are to be maximized then a full understanding of user skills, motivations, preferences and learning profile is required. We propose that this detailed understanding is best informed by adopting a psychological perspective on the mobile learning process. Therefore this article considers the insights that can be derived from viewing mobile learning through a psychological lens: in particular the psychological challenges that mobile learning presents and the importance of considering individual differences in learner skills and behaviours. We will also consider the insights that psychology offers in addressing these challenges, especially the importance of media literacy skills, the presentation of learning resources in a way that considers the limited cognitive resources of the learner and the importance of context and contextualized behavior. In so doing, we demonstrate the persuasive case for embedding psychologically driven insights in future multi-disciplinary research and practice.

BACKGROUND: APPROACHES TO MOBILE LEARNING

Rapid technological advancements are substantially influencing the educational landscape, of-

fering learners, providers and developers a range of new platforms for learning. One of the most exciting platforms is mobile learning. Mobile learning can be defined as the use of wirelessly connected devices to augment learning and teaching within and between different psychological, social, physical and temporal contexts. Mobile learning has recently been identified as one of the key facilitators of learning across the globe (UNESCO, 2013). If these learning opportunities are to be maximised then a detailed understanding of the determinants and influences on uptake, use and effectiveness is required. Just as educators have to understand how we learn in traditional contexts, we now have to understand how we learn using mobile devices. Psychology is well placed to offer detailed insight into the necessary skills, preferences and behaviours necessary for successful mobile learning to occur. In the following section we outline the different perspectives on mobile learning.

The evidence base for mobile learning is rapidly developing and reflects understanding of the nature, process and influences on mobile learning from a number of different, but often complementary, perspectives. One of the first and most influential approaches is that of Mike Sharples who advanced an early definition in his seminal paper on mobile lifelong learning: “a new genre of educational technology - personal (handheld or wearable) computer systems that support learning from any location throughout a lifetime” (Sharples, 2000, p.177). Sharples sub-

sequently developed guidelines for the design and delivery of mobile teaching and learning which emphasised how mobile learning is different from other forms of learning and how learners “artfully engage with their surroundings” (Sharples, Taylor and Vavoula, 2007, p.2), be observant of state of the art best practice and of the availability of personal technologies. This latter point was further emphasised by Vavoula and Sharples (2008) in their recognition of the distinguishing role of context for mobile learning, in particular for the need to evaluate learning in and across the contexts in which it occurs. More recently, mobile devices have been found to be effective in supporting enquiry-based learning both within and beyond formal scheduled learning contexts (Sharples et al, 2015). Roleplay-based games delivered via short messaging (SMS) have also proven instrumental in the development of the critical thinking skills of peer educators (Roy and Sharples, 2015).

The situated, contextual nature of mobile learning is also recognised by Norbert Pachler who in collaboration with Bachmair, and Cook (2010) takes an ecological stance on mobile learning by emphasising the importance of “understanding and knowing how to utilize our everyday life-worlds as learning spaces” (p. 6), thus highlighting the role of sociocultural influences upon learning behaviour. More recently, the importance of understanding the specific affordances of mobile learning and the role of mobile devices as “cultural transformational tools” (p. 938) has been emphasised in mobile learning design, in the quest to design for it appropriately (Bannan et al, 2016). The use of mobile technology and the learning opportunities it offers for young children within the context of the home has been examined by Marsh (2015) who investigated family practices concerning mobile technologies such as laptops, tablets, and mobile phones in and around the home and found that children typically use a mobile device such as a tablet alongside a parent, rather than alone. Research evidence indicates that parents play an important enabling role guiding and educating their children’s use of technology and may also

act as role models for its use. For example, parents’ actual use of mobile media (i.e. their behaviours), as opposed to their attitudes towards their child’s use is, in part, predictive of their child’s use (Lauricella et al. 2014; Terras, Yousaf and Ramsay, 2016). Such findings highlight the importance of taking an ecological, contextually-informed approach to the mobile technology use of learner of today but also of considering the learners of the future, as ecological contexts influence the development of skills, practices and attitudes.

A different perspective on mobile learning, which is more educational in emphasis, is offered by John Traxler who defined mobile learning as “the provision of education and training on PDAs/palmtops/handhelds, smartphones and mobile phones” (Traxler, 2009, p.2). Traxler’s focus is on formal learning and he observes that access to information when one is mobile is leading to a reconceptualization of what it means to be trained and what it means to be supported in doing one’s work. Traxler (2007) also makes the incisive point that “mobile” does not merely describe the manner in which one learns, rather it now heralds a reconceptualization of what it means to learn. The notion of a reconceptualization is a very important one for educators as it points to a fundamental shift in the nature of education that may, arguably, introduce new and as yet unidentified pedagogical and psychological challenges for learners. In the introduction to a recent special edition on mobile-assisted language learning, Traxler et al (2016) made the insightful observation that “Mobile learning might, in fact, not be the mobile aspect of learning so much as the educational aspect of mobility” (p. 1235). This insight lies at the heart of the growing appreciation that time, space, place and manner of activities (whether learning or other) need to be characterised and understood to ensure that they capture the rich and dynamic nature of human behaviour whilst mobile. Only by doing so will the educational potential be captured.

An influential approach on mobile learning is that of Agnes Kukulska-Hulme who emphasises

the evolving nature and use of mobile devices and user preferences: in particular the fact that mobile learning often occurs via devices that may not have been intended to support learning (e.g. smartphones) which reflects the natural and informal way in which mobile learning has developed (Kukulska-Hulme, 2007). Kukulska-Hulme and Jones (2011) have advocated the integration of an understanding of learner practices, learning contexts, and technologies within pedagogical approaches. Kukulska-Hulme (2012) also considers the question of learning being defined by the time and place within which it occurs and therefore argue for frameworks to organise these new ways of learning. Pedagogies of mobile learning should recognise and potentially capitalise on the dynamic, changing sociocultural context(s) of learning and the highly individual, situated and learner-initiated nature of the learning that takes place. They also need to be cognisant of the social communication and interpersonally constructed models of understanding and knowledge generation that characterise any Web 2.0 applications.

Whilst clearly reflective of the situated, ecological perspective taken by Pachler, the psychological nature of Kukulska-Hulme's arguments also complement well the more explicit psychological perspective taken by Terras and Ramsay, especially in the identification of contextual factors including the importance of the temporal dimension outlined below.

A Psychological Perspective on Mobile Learning

Terras and Ramsay (2012) have leveraged the potential of psychological concepts, theory and method to assist in mapping the challenges of the mobile learning landscape from the perspective of learner *behaviours* and the psychological infrastructure that underpins them. The five psychological challenges reflect well-established constraints that limit human cognitive functioning and behaviour: (1) memory is often context dependent, (2) information processing resources

are finite, (3) cognition is distributed in nature, (4) self-regulation and meta-cognition are essential for effective learning and (5) importance of recognising individual differences in learner skills and preferences.

This unique Psychological perspective not only differentiates their proposals from other researchers in the field but also offers a way to integrate research in the area. Terras and Ramsay argue that it is by conceptualising the issues raised by their contemporaries, in psychological form, that the field of mobile learning will be in a position to advance. The quest to understand the complex, embedded nature of mobile device use, along with an appreciation of the need to recognise both formal and informal styles of usage across changing contexts, offers a way to integrate the differing perspectives on mobile learning. The key issues raised by their peers in the field, such as transfer, personalisation, time and context (Kukulska-Hulme), the re-conceptualisation of what is meant by training (Traxler), the need for guidelines for mobile learning (Sharples and Vavoula), the need to evaluate mobile learning across contexts and understand how learners engage with their surroundings (Sharples), and the need to understand everyday worlds (Pachler) *can all be rendered in psychological form as challenges* to be addressed by the field. Terras and Ramsay argue that it is by laying bare the underlying, commonly-shared psychological mechanisms that underpin mobile learning across time and context that a sufficiently nuanced understanding of the nature of mobile learning as an emergent form of learning will be realised.

The Psychological Challenges of Mobile Learning

Just as educators have to understand how we learn in traditional contexts, it is now necessary to understand how we learn using mobile devices and Psychology is well placed to offer detailed insight into the necessary skills, preferences and behaviours necessary for successful mobile learn-

ing to occur. The following sections provide an overview of the challenges, the insights that a psychological approach can bring, and the solutions it offers.

As discussed above, Terras and Ramsay (2012) identified five major psychological challenges to mobile learning:

1. The challenge of context dependence: stimuli and cues that assist with the development and consolidation of learning exist within the very fabric of our environment. Perhaps most challenging of all, is the ever changing nature and intermittent presence of these contextual cues.
2. The challenge of finite information processing resources: the ability to hold information mentally so that it is ready to use – this is known as working memory capacity, and the ability to remember intentions i.e. future actions- prospective memory. Both extremely vulnerable to overload from contextual or environmental factors and this vulnerability may have a detrimental impact on mobile learning given its' situated nature.
3. The challenge of distributed cognition: cognition, namely, our mental models, plans and understandings of the world do not exist within the confines of our individual selves. Rather, for such models and plans to be of use, they are necessarily shared in various forms between individuals. Communication is at the heart of what it means to be human, and in communicating, we co-create commonly shared models of how the world is. These common understandings are not carbon copies, rather, they exist in versions within different individuals. Additionally, common understandings and representations of how the world is, are maintained not only across groups of individuals, but also across time. It is memory that allows us to do this, but it is not without its challenges. It has long been established that human memory is subject to very many influences. This, in

turn, introduces a further complex consideration, to the distributed nature of human cognition.

4. The challenge of self-regulation and meta-cognition. Self-regulation refers to the ability to be aware of one's own behavior, desires and impulses, and to manage them in a socially appropriate manner. This is done through a combination of introspection and evaluation of social norms, which requires an understanding of the needs and expectations of other people. Metacognition, namely thinking about thinking, is a higher-order form of cognitive control that allows the individual to manage their cognitive resources (their mental processes) to achieve better outcomes. Mobile learners need to become more self-aware and self-evaluative: they need to be sensitive to how their learning is affected by both internal factors such as their own cognitive skills and preferences and the influence of external factors such as the nature and content of formal and informal learning resources and the more general external context (Hu and Zhuang, 2011; Terras and Ramsay, 2012; 2014).
5. The challenge of accommodating learner differences. It has long been established in the field of Psychology that human beings are individually different. Whilst there exist patterns, likelihoods and tendencies that are associated with particular behaviours across large groups of people, it has nevertheless been established that learners are individually distinct. Indeed, learning whilst moving through individually-steered social, virtual and geographical contexts adds a significantly deeper complexity to the challenge of characterizing individual mobile learners.

The Spatio-Temporal Context of Mobile Learning

The changing spatio-temporal contexts of mobile access can present increased psychological de-

mands for learners. Therefore, Terras and Ramsay extended their conceptualisation of context to include a more detailed consideration of the temporal dimension of mobile learning and the temporal aspects of the five initial challenges (Terras and Ramsay, 2014a; 2014b). It is essential to explicitly consider the temporal aspects of mobile learning because (i) change in location occurs over time, and (ii) time may be experienced differently depending on the context. Given that time and locational change are often closely linked, consideration of the changing locations supported by mobile access must be situated within the wider temporal context. In order to do so, it is necessary to distinguish between the physical and subjective aspects of time during the mobile learning experience (Terras and Ramsay 2014a; Terras and Ramsay, 2014b). Physical or objective time, is how time is generally conceptualised: it is fixed, linear and is measured in standardised units such as seconds, hours and days. Psychological or subjective time is context dependent, non-linear and does not extend from the objective “past” to “present” (Zaky, 2012). The subjective experience of time is unique and is a product of cognitive, emotional or psycho-social influences (Droit-Volet and Gil, 2009). From a psychological perspective, consideration of the temporal dimension of mobile learning highlights the “importance of considering a learner’s experience of time, how contexts changes over time, the retrospective and prospective aspects of time, the importance of the sequencing of information over time and how information, knowledge and understanding are distributed across time” (Terras and Ramsay, 2014a, p. 114).

Mobile learners need to be aware of the spatio-temporal context. The concept of context-awareness is addressed in computer science as part of a system that keeps track of location (Dey, 2001); in a mobile context the best known example of a context-aware system is the mobile tourist guide. However, a more comprehensive and user-centred, rather than system centred perspective i.e. how mobile learners perceive context is required to inform good design and promote good mobile learning

skills. Five aspects of context have been identified: time, location, identity, activity and relationships to other entities and objects. Empirical data indicates that people are sensitive to the temporal aspects of contexts (Crane et al, 2011) but less is known about how this monitoring takes places, how it may vary across different contexts and how it may be influenced by the motivations and goals of the learner or the activities they are engaged in (Terras and Ramsay, 2014b).

Solutions and Recommendations: Psychological Insights and Solutions

Instructional Design

To date, psychological theory and research has offered immense insight into the design of effective e-learning resources by ensuring that instructional material is sensitive to the processing constraints of the human cognitive system thereby, avoiding cognitive overload. There are three types of cognitive load: intrinsic cognitive load, extraneous cognitive load, and germane cognitive load (Sweller, 1988). Intrinsic cognitive load reflects the processing necessary to undertake a task i.e. the processing load or task difficulty is inherent to the task. Germane load refers to the working memory resources that are required to deal with intrinsic cognitive load. Extraneous cognitive load is external to the task and can therefore be manipulated, ideally being kept to a minimum. Extraneous load is most often dependent on the format of the information presented e.g. describe a shape or show a picture of the shape. Therefore, instructional material should impose the lowest possible extraneous cognitive load in order to free our limited resources to process the content. Another influential load-based theory is the Cognitive Theory of Multimedia Learning which utilises a concept very similar to cognitive load, termed *Demands for Cognitive Processing* to highlight the dangers of overload (Mayer and Moreno (1988; 2003) by drawing upon a classic psychological theory concerning the nature and

structure of the cognitive system: Paivio's Dual Coding theory which posits dual information processing channels: one for visual and another for verbal information (Paivio, 1986). From a learning perspective, information can be acquired from both words and images, but our ability to process information in either visual or verbal format is limited, and if we become overloaded then we will fail to learn.

Cognitive overload is especially significant when designing mobile learning materials. Although designers can control the content of formal learning materials, the changing spatio-temporal contexts associated with mobile learning, place more control in the hands of the learner resulting in the possibility of overload, and this increased if they accessing informal learning materials which must be managed by the learner. More recently psychologically-based research has highlighted the importance of considering individual differences in a learner's cognitive profile, especially their working memory capacity. Problematic mobile device usage is associated with a lower ability to manage distractions, along with having poorer working memory capacity and weaker attentional control (Hadlington, 2015). Learners with low working memory capacity often achieve poorer outcomes than learners with high working memory capacity when they had to divide their attention across a mix of audio, text and images (Fenesi, Kramer & Kim, 2016).

Motivations for Use

Psychological theory and research has also provided considerable insight into the reasons and motivations for use of technology, both static and mobile through the Technology Acceptance Model (TAM) and its associated refinements. The Technology Acceptance Model (Davies, 1981) explains why people do, or in some instances do not, use technology by drawing upon well-established psychological constructs to understand and predict behaviour: The Theory of Reasoned Action and the Theory of Planned Behaviour (Fishbein and

Ajzen, 1975). The theory of Reasoned Action draws upon three psychological constructs: Behavioral Intentions, Attitude towards the behavior and the Subjective norm: behaviour is determined by the Intention to perform it, and this Intention is determined by a person's attitude toward the behaviour and the subjective norms of the behaviour. These proposals were further refined by the Theory of Planned Behavior (Ajzen, 1985) with the inclusion of the additional construct of Perceived Behavioral Control to extend the remit of the theory to include behavior under non-volitional behavior. The theory of planned behavior predicts that more positive Attitudes, supportive Subjective norms and high degrees of Perceived Control, the stronger the behavioral intention, therefore the behavior is more likely to occur. When applied to the uptake of mobile learning in higher education, 87.2% of the intention to use mobile learning was explained by the three key factors of Attitude, Subjective norm and Behavioral control, with Perceived behavioral control as the strongest predictor of the mobile learning uptake (Cheon, Lee, Crooks and Song, 2012). Using structural equation modelling Park et al (2012) examined the utility of a TAM based explanation of mobile learning that included the following components: independent (exogenous latent) variables were individual factors such as mobile learning self-efficacy, major subject studied, organisational factors (e.g. accessibility of the mobile learning system), and social factors reflecting the subjective norms. The outcome (endogenous) variables were perceived usefulness (PU), perceived ease of use (PE), mobile learning attitudes and behavioral intentions. The endogenous variables reflect three psychological domains: cognitive, affective and behavioral. The results indicate that behavioral intention and actual use is determined by four main groups of variables: individual context, system context, social context and organisational context. Clearly illustrating how the psychological constructs of the TAM model allows the prediction of direct and indirect influences on students' intentions to use mobile

learning (Park, Nam and Cha, 2012). Based on the TAM model Park et al make three practical recommendations: (1) Promote positive attitudes to mobile learning and emphasize its relevance as Attitudes we shown to have the largest direct effect on mobile learning behavior, social norms too were directly related to behavior. (2) Good wireless facilities and the provision of either devices or subsidies of mobile devices are essential as System Accessibility was another factor that directly influenced Behavioral Intention. (3) Provide support (e.g. mentoring) to enable students to use mobile learning. The model indicates that mobile learning self-efficacy affects both attitudes and perceived effort, with perceived effort influencing perceived usefulness which in turn affects attitudes. It is clear that psychologically driven theories offer a way not only to conceptualise and explore the challenges of mobile learning but also offers practical ways in which these challenges may be overcome.

Skills: How to Learn and Media Literacy

If mobile learning is to be effective, then learners must possess and apply the relevant skills: they must know how to learn using mobile technology and its associated learning resources. It should not be assumed that just because learners can use technology, especially social technology, that they will be effective mobile learners (Terras, Ramsay & Boyle, 2011). They may require explicit instruction on how to use technology to learn to help them overcome the specific psychological and practical challenges presented by mobile learning (Ramsay and Terras, 2015). The challenges presented by changing spatio-temporal context and the increased contextual awareness necessary have already been noted, and these challenges may be exacerbated by multitasking. In recent years, the increasing sophistication of wireless internet access means that technologies such as telephones and personal computers (PCs) have undergone a uni-function to multi-function

shift e.g. mobile telephones now not only support verbal communication, but also internet access and all the opportunities it affords such as email, video calling, social networking and the accessing of formal educational resources such as virtual learning environments (VLEs) and Massive Open Online Courses (MOOCs) as well as more informal user-generated resources typified by YouTube and Wikipedia. It is now possible to not only multitask across different devices, but also multitask on the same device. Hence learners may require increased sensitivity to their own multitasking ability, especially as people often overestimate their ability to multi-task (Sanbonmatsu et al. (2013), advice on how to allocate or inhibit attention across competing tasks, and instruction on how to use a mobile device which they generally use for social purposes to support learning. Frequently these situations may co-occur and they must be managed by the learner. For example, students frequently multitask on Facebook during self-directed study (Judd, 2014) and also in class which often result in poorer academic performance (Junco, 2012). Raising learners' awareness of their behaviour and its associated consequences may prove useful, as could instruction and use of active study and meta-cognitive strategies as well as 'technology breaks' (Rosen et al, 2013).

The ability to create, interpret and evaluate informational content is a key skill for effective learning. Various terms have been used to capture these skills, most notably media, digital or participatory literacy. The concept of media literacy is the most relevant, both now and in the foreseeable future to capture the skill set necessary for effective mobile learning as it is broad in focus (Ramsay & Terras, 2016). Media literacy is defined by the United Kingdom's telecommunications regulator as "the ability to use, understand and create media and communications in a variety of contexts" (Ofcom 2015, p. 19). Therefore, media literacy skills operate across a wide range of technology such as television, games, smartphones, internet and social media in a variety of work, social and educational settings all of which are relevant to

the mobile learner. Like print literacy, media literacy is generally viewed from two distinct perspectives: skill or social practice. An influential skills-based approach in higher education is that taken by the Joint Information Systems Committee (JISC) who identify a multi-component skill set under the umbrella term of Digital Literacy (JISC, 2014). The wide remit of the JISC approach highlights the complex nature of the skills required to benefit from technology-enhanced learning. In contrast, media literacy can be viewed as a social practice which emphasises how skills develop as individuals interact with their environment and how these interactions are dynamic and reciprocal (Livingstone, 2015). Considering skills in context encourages the consideration of contextual influences and individual differences. In order to fully understanding the skills necessary for effective mobile learning it may be more productive to adopt a blended approach that situates skills within their socio-ecological contexts (Ramsay & Terras, 2016).

FUTURE RESEARCH DIRECTIONS

Technological change and mobile learning provision is moving at a fast pace, so future research should be informed by technological advances, pedagogical theory and practice, psychological insights and to maximise potential of both research and practice, interdisciplinary working *to develop* an holistic understanding of the mobile learning experience.

One of most exciting advances with huge potential to enhance the mobile learning experience is “big data”: Data that can be gathered about learner behaviours including which type of information they access, how it is accessed, where, time spent on learning activities, the format or media that is used for different activities, achievement of learning outcomes, grades and similar information. This learning analytical data can be used to develop patterns of learner behaviour to provide insight

into learner behaviour and support formative reflection by learners and evaluations by providers.

Specifying the psychological challenges of mobile learning not only adds to our understanding of the process, but also helps identify how learners can be supported. The information discussed here highlights that learners may need to be taught how to learn using mobile technology and how to overcome both the practical and psychological challenges of learning in contexts that change across both space and time. The most effective intervention will be psychologically informed and support the psycho-social and cognitive factors that underpin necessary skills such as metacognition, self-regulation, self-efficacy and motivation as they allow students to govern their own learning.

CONCLUSION

The potential of mobile learning is rapidly being recognised and maximised as evidenced by the work of Sharples, Kukulska-Hulme, Terras and Ramsay, Traxler and Pachler and other colleagues across the globe. However, irrespective of the approach taken, it is essential that the psychological challenges that mobile learning presents are also recognised and addressed. Although many of these psychological challenges are attributable to limitations inherent in the human information processing system adopting a psychological perspective allows plausible and effective solutions to be developed. Cognitive load-based theories inform the design of learning materials and the Technology Acceptance Model helps identify factors that influence the uptake of mobile learning. Considering the experiential perspective of the mobile learner emphasises the importance of contextual awareness and the need to support the necessary skills to learn and monitor and control both external and internal contexts to ensure effective mobile learning. A detailed appreciation of individual learner skills and preferences will become increasingly important when mobile learn-

ing takes advantage of the opportunities afforded by Web 3.0 and the “semantic web”, where individualised profiles can be used to inform search results. Understanding the psychosocial profile of mobile learners will be essential for the provision of fluid and effective personalised learner experiences in the future. Psychologically-driven theory and research has contributed greatly to our understanding of the mobile learning experience to date and we expect it will continue to do so in the future.

KEY TERMS AND DEFINITIONS

Cognitive Constraints: Refer to the finite nature of human mental processing.

Context Awareness: To the ability of a human or a technology to characterise and exploit knowledge about its current environment.

Media Literacy: Ability to access, evaluate and create content effectively and responsibly via different media types.

Meta-Cognition: Thinking about thinking – the ability to control, manage and manipulate one's mental processes.

Mobile Learning: Mobile learning refers to use of handheld devices such as mobile phones

and tablets to access both formal and informal (e.g. general internet-based information) learning resources.

Psychological Challenges: Refers to the difficulties and obstacles that mobile learners encounter due to their finite mental processing ability.

Psychological Time: This is the subjective experience of time i.e. how time is perceived by the individual. It contrasts with objective or physical time that is conceptualised in standardised units such as seconds, hours and days.

Psychology: The scientific study of human behaviour.

M

The Role of Distance Education in Global Education

Kijpokin Kasemsap

Suan Sunandha Rajabhat University, Thailand

INTRODUCTION

Distance education mainly serves learners who cannot attend the face-to-face courses or programs for one or another reason (Ekmekçi, 2015). Learners stay at home or office and follow the course, do the assignments, and interact with each other and the teacher via the Internet (Ekmekçi, 2015). Distance education contributes to a large portion of the population has access to education and represents a possibility of meeting the new formative demands arising apace, with the adoption of a teaching format that is not restricted to classroom activities and mainly due to its low cost and its high degree of flexibility enables the approximation of the long distances and the democratization of access to education for learners seeking the better use of time, compatibility, and flexibility of schedules, geographic independence, among other learners (Rodrigues, Affonso, Quinelato, & Montiel, 2014).

Lifelong learning and knowledge management are practically directed at employment, career opportunities toward continuing professional education for both employed and unemployed people (Kasemsap, 2016a). Distance education develops in the field of technical education, which is connected with the characteristics of the educational material of humanities disciplines, difficult to formalize and, secondly, with the greater competence of pedagogic staff of technical education in the utilization of new information and communication technology (ICT) and modern software (Nurmukhametov, Temirova, & Bekzhanova, 2015). Distance education course formats can alter the

modes of information exchange and interpersonal interaction related to traditional course formats (Mackey & Freyberg, 2010). There has been an explosive growth in distance education which is rapidly transforming the traditional learning habits with the more recent ones utilizing the latest educational technology (Paksoy, 2015).

This article aims to bridge the gap in the literature on the thorough literature consolidation of distance education. The extensive literature of distance education provides a contribution to practitioners and researchers by describing the current issues and approaches in distance education to appeal to the different segments of distance education in global education.

BACKGROUND

For the last twenty years, many universities and educational institutions tried to find the new ways and methods in order to effectively utilize the Internet-based technologies in teaching and learning through the distance education initiatives (Altunisik, 2013). The increasing educational demand, time limitations, and geographical obstacles practically increase the demand of distance education (Ilgaz & Askar, 2013). With the development of Internet technologies, online distance education is becoming an important format for teaching, learning, and instruction (Li, 2007). Internet technologies are realized that they can employ in the training system and they are recognized as the educational facilitator in the distance education (Çelik, Ferikoglu, Kiraz, Albayrak, &

Ekiz, 2013). Distance education, having arisen at the end of the 20th century, enters the 21 century as one of the most effective systems of learners' training (Lenar, Artur, Ullubi, & Nailya, 2014).

Education in the 21st century requires the implementation of innovation in the teaching technology (Malganova & Rahkimova, 2015). In parallel with the recent developments, education has initiated to utilize the Internet media (Çelik et al., 2013). Distance education exploits the Internet intended for course supply for the students and educators in the different locations (Paksoy, 2015). Learners electronically interconnect with the educators in global education (Sims, Dobb, & Hand, 2002). Regarding distance education, course content can be presented through the recorded lectures, slide presentations, text-based documents, interactive online activities of various forms, audio files, video files, pod casts, wikis, live chat sessions, online discussions, live online presentations, videoconferencing, and other methods. Video cases can capture the complexity of the classroom context and provide the efficient way to expose the learners to the authenticity of the classroom (Bayram, 2013).

The emergence of worldwide communications networks and powerful computer technologies has redefined the concept of distance learning and the delivery of engineering education content (Bourne, Harris, & Mayadas, 2005). Distance education continues to have a significant impact on higher education (Hollis & Madill, 2006). With pressures to increase the access to higher education, colleges and universities have focused on increasing the number of online courses and educational programs offered (Meyer, 2014). Distance education can overcome the barriers to the learning (e.g., time limitation and geographical location) and provide the online communities of practice in circumstances where different factors make it difficult (Siri & Rui, 2015).

Distance education, with its growing availability and reduced intrinsic costs, becomes more prevalent in global education (Buxton &

De Muth, 2013). Distance education technologies are considered as the major factors promoting the development of network interaction for the educational institutions (Mozhaeva, 2014). Distance education is developed in order to meet the needs of learners who cannot participate in the face-to-face classes (Beldarrain, 2006). Many distance education courses have been created and disseminated by using the Internet or similar network systems in support of pedagogical communication concerning technical improvement to the undergraduate and postgraduate students (Rodrigues et al., 2014).

Distance education has been recognized as an effective pedagogical method and tool, and is broadly integrated into various types of teaching and learning strategies in higher education (Park, 2011). Regarding distance education, digital libraries comprise digital collections, services, and infrastructure to educationally support the lifelong learning, research, and conservation of the recorded knowledge (Kasemsap, 2016b). Continuing professional development is the training and education that continues throughout an individual's career in order to improve the skills and knowledge (Kasemsap, 2017a). Educational computer games can motivate students to develop the basic competencies and encourage challenging themselves to be better and learn the additional knowledge related to the important tasks (Kasemsap, 2017b).

Advances in multimedia and Internet technologies have generated the explosive growth in distance education (Hay, Peltier, & Drago, 2004). Online activities and educational tools (e.g., multimedia and discussion boards) increase the emotional engagement in distance education (Sun & Rueda, 2012). The Internet and multimedia, including the non-linear integration of video, audio, text, and graphics can provide the rich environment for case studies which promote the mental construction of knowledge toward integrating the modern technology into the curriculum (Cannings & Talley, 2002). Multimedia,

a computer-based application, the normal text, audio, images, graphics, animation, video, and the supported use of visual encouragement is the perspective of the user interface in distance education (Bourne et al., 2005).

ADVANCED ISSUES OF DISTANCE EDUCATION IN GLOBAL EDUCATION

This section emphasizes the overview of distance education and the importance of distance education in global education.

Overview of Distance Education

Distance education is defined as the learning process in which individuals have the opportunity for learning, independent from time and place, and in which various techniques are used in the learning activities (Kor, Aksoy, & Erbay, 2014). Distance education is defined as the process of extending learning, or delivering instructional resource-sharing opportunities, to locations away from the classroom, building or site by using video, audio, computers, multimedia communications, or some combination of these with other traditional delivery methods (O'Neil, Fisher, & Newbold, 2009). Web-based distance education has become an economically viable option, due to the near universal availability of computers in the workplace and home, and to technology improvements (Buxton & De Muth, 2013).

Distance education makes the learner effectively learn through the technological tools (Rashid, Khokhar, & Tahir, 2013). Eisinger (2000) stated that distance education is the planned learning experience toward encouraging the student's communication. The most widely used presentation systems in distance education are the printed materials, television broadcasting, broadcasting via microwave, and other electronic methods, such as computer conferencing, audioconferencing, and

videoconferencing (Keating, 2006). Despite long distance between the learning and teaching groups, the educational groups have the opportunity to learn in the virtual classes, similar to traditional classroom setting, through computers with Internet connection (Kor et al., 2014).

With the growing popularity of distance education opportunities, students' attitudes toward distance education is rapidly changing (Çelik & Uzunboylu, 2015). Service quality of distance education applications in the education sector can be investigated through five service quality determinants (i.e., tangibles, reliability, responsiveness, credibility, and empathy) (Dursun, Oskaybas, & Gokmen, 2013). Satisfaction with learning, level of control of the learning process, and study motivation for distance education are positively related to the students' preferences for the structured distance education (Katz, 2002). Online communication, electronic work submission, and online meeting capabilities mean that participants can complete the courses without attending the class in the university (Allworth, 2014).

Importance of Distance Education in Global Education

Distance education is a significant topic of discussion within institutions at all levels of education (Annetta & Shymansky, 2006). The rapid spread of distance education in the world not only offers learners and teachers great opportunities but also brings a lot of challenges (Ekmekçi, 2015). Distance education is the economic and interactive education perspective using information technology (Çelik et al., 2013). Distance education is among the significant fields for the application of educational technology (Ding, Niu, & Han, 2010). Activities in the field of distance education have shown a significant improvement in the world (Kor et al., 2014). Distance education students have opportunities to structure their own learning contexts as they engage with individuals in their everyday environment (Ferguson, 2010).

Distance education has become deeply embedded in the offerings of most community colleges (Milam, Voorhees, & Bedard-Voorhees, 2004). Distance education allocates importance to interaction, thus establishing several distance education environments (Ergül & Koç, 2013). Distance education relies heavily on self-learning and self-learning resources, although the interaction at the designated learning centers and online learning platforms are occasionally offered (Zhao, Chen, & Panda, 2014). Learning communities can provide learners with an educational environment conducive to the increased interactions and alleviate their feeling of isolation (Yuan & Kim, 2014). The learner-learner interaction concentrates on technology-enhanced learning using video communications which provide opportunities for more authentic online collaborative learning (Smyth, 2011).

In distance education, the most common interaction-enabling activities are forum and chat (Scarinci, 2015). The size of the demand for higher education both in terms of campus or open and distance education, depends on the employment opportunities of the graduates more than the offered training programs and the images of the educational institutions (Berberoglu, 2015). Distance education provides access to education with satellite, video, audio, graphics, computer, multimedia technology with the support of electronic devices (Çelik et al., 2013). Computer-computerized systems (e.g., laptops, tablets, and smartphones) enable the establishment of the educational programs from which the learners can get education by utilizing the Internet (Çelik & Uzunboylu, 2015). Educators normally use distance education for delivering the entire courses and the educational programs worldwide, or for providing the learning experiences for educational courses, staff development, and continuing education (Billings, 2007; Hyde & Murray, 2005).

In order to deliver the library instruction and promote the library resources to the distance education students, distance education librarians

often take advantage of computer applications to produce the audio/video and web-based tutorials (Tang, 2013). Distance education librarians also use the videoconferencing and the virtual classroom technology to teach the information literacy (Tang, 2013). In the concept of distance education, the remote controlled laboratories and the virtual laboratories provide an educational opportunity for the laboratory work by the remote control of the real laboratory equipment in global education (Stefanovic, 2013). Distance education can contribute to the health care professionals' practice knowledge (Moule, Ward, & Lockyer, 2010). Distance education significantly decreases the cost of academic health education at all levels (Mattheos, Schitteck, Attström, & Lyon, 2001). Distance education can take a variety of forms including in the health professional education concerning the simulations of clinical scenarios (Tait, Tait, Thornton, & Edwards 2008), the Internet-based discussion boards, and the role play (Nelson & Blenkin, 2007).

FUTURE RESEARCH DIRECTIONS

The classification of the extensive literature in the domains of distance education will provide the potential opportunities for future research. E-learning allows students to choose content and tools appropriate to their differing interests, needs, and skill levels (Kasemsap, 2016c). Web-based learning supports the open learning concept by providing students with the ability to connect to the educational resources when it is convenient for them, and allowing students to explore the educational resources in an effective order that suits their educational needs (Kasemsap, 2016d). Learning analytics can gather data, analyze data, generate reports, and enable interventions in the modern educational world (Kasemsap, 2016e).

Regarding mobile learning, the widespread adoption of mobile devices coupled with the powerful computational and communication capacity of convenient mobile devices promises

a fundamental shift in learning and knowledge work. Mobile learning often takes place outside a formal learning environment, and it tends to become personalized through users' personal mobile devices. Educational computer games educationally create learning experiences, provide personalized learning opportunities, and encourage a learning environment for authentic and relevant assessment in the game-based learning environment. Future research direction should broaden the perspectives in the promotion of e-learning, web-based learning, learning analytics, mobile learning, educational computer games, and distance education in the modern learning environments.

CONCLUSION

This article highlighted the overview of distance education and the importance of distance education in global education. Distance learning becomes an alternative to traditional classrooms. Students can benefit from the flexibility, convenience, effectiveness, and affordability that come with distance education. For students who do not have the time or money to attend the traditional schools, distance education can provide a path to higher education. Distance education can increase the opportunities for students across the globe, ensuring that students do not have to choose a school based on its location.

Because of the high level of flexibility that an online program offers to people all over the world, it is common to network internationally as a result of program participation. One of the benefits of distance learning is that there is a wide variety of materials that can meet everyone's learning preference, at least part of the time. Distance education enables students to work at their own pace in many circumstances, and leads to networking with an even wider variety of people than you might encounter at a local institution. Facilitating

distance education has the potential to improve educational performance and gain sustainable competitive advantage in global education.

KEY TERMS AND DEFINITIONS

Distance Education: The learning that uses television, video tapes, computers, and Internet, instead of physical attendance at classes in a centralized facility.

Education: The wealth of knowledge acquired by an individual after studying the subject matters or experiencing life lessons that provide an understanding of something.

Information Technology: The science and activity of using computers and other electronic equipment to store and send the information.

Internet: The worldwide computer network that provides information on many subjects and enables users to exchange the messages.

Learning: The measurable and permanent change in behavior through experience, instruction, and study.

Multimedia: The integration of animation, audio, graphics, text, and full-motion video through computer hardware and software for education, entertainment, and training.

Technology: The use of scientific knowledge to solve the practical problems, especially in the industry and commerce.

INTRODUCTION

With the growth of access to technology, the limitation of the traditional hypermedia applications has become evident: it provides the same contents and links to all users, disregarding their profiles and individual characteristics. Considering a diverse user population, the traditional system is not able to be “all things to all people”, since students with different goals will need different explanations, readers with different interests will enjoy different books and visitors with different knowledge will avail different curiosities about a place (Brusilovsky, 2001). An attempt to bypass the negative effects of the “one-size-fits-all” approach is in providing these systems the ability to adapt themselves according to the needs of the individual user (Brusilovsky et al., 1998).

Based on that, Adaptive Hypermedia (AH) systems are all hypertext or hypermedia systems that reflect some features of the user (e.g., goals, preferences and knowledge) in a user model and modify their various visible aspects according to this model (Brusilovsky, 1996). When hypermedia records and stores learners’ preferences, individual needs and learning goals, using them throughout interaction in order to meet their personal needs and to promote a better learning, then hypermedia

becomes AH (Turel, 2015). To be considered an AH, the system should satisfy three criteria: being a hypermedia (or hypertext) system, having a user model and using this model to adapt the hypermedia (Brusilovsky, 1996).

In order to meet the first criterion, the system should store all information into small units (usually called nodes) containing text (hypertext) or other forms of information (hypermedia). These units are presented one per window, being interconnected by links that allow users to navigate in a predefined way (Akscyn et al., 1988). To meet the second criterion, it must have a model where data about the users (e.g., knowledge, interests, goals and individual traits) are stored (Brusilovsky & Millán, 2007). Finally, the AH system must adjust its presentation – content (defining the most relevant contents to each user and how to structure them) and interface (making a presentation more efficient and meaningful to the user) (Bunt et al., 2007) – and navigation (guiding the user in the hyperspace through the selection and presentation of the most important links in order to continue the navigation system) (Brusilovsky, 2007) based on the data to be stored in the user model.

There are different application areas to AH systems, e.g.: Educational Hypermedia, On-line Information, On-line Help, Information Retrieval,

Institutional Information, Personalized Views, etc. The AH educational systems goal is to create an instructionally sound and flexible environment that supports learning for students with a range of abilities, disabilities, interests, backgrounds, and other characteristics, enabling students to learn as much as possible on the available material (Shute & Zapata-Rivera, 2012).

The aim of this chapter is to present Adaptive Hypermedia Systems fundamentals and trends. To achieve it, section 2 introduces the background about user modeling. Section 3 describes some methods and techniques that allow adaptation. Section 4 illustrates some of the existing AH systems. Section 5 points out trends and future directions and Section 6 concludes this work.

BACKGROUND

User model is the representation of information about an individual user, which is essential to make the AH system behave differently according to each user. Based on this model, the AH system can prioritize the most relevant results of a search, manipulate links to facilitate the navigation and present the content adaptively. During the user modeling, the amount and nature of the sorted user information depends on the kind of adaptation effect the AH system has to deliver (i.e., content, presentation and/or navigation) (Brusilovsky & Millán, 2007). The most common stored data are described below based on Brusilovsky & Millán (2007) and Schiaffino & Amandi (2009).

- Knowledge about the application domain enables proper assistance or content adaptation. The users' knowledge is a changeable feature that can increase (i.e., learning) or decrease (i.e., forgetting) from time to time. The AH system must recognize this change and update the user model to provide a more reliable and assertive adaptation. The knowledge about each element can be represented in binary form (i.e., knowing or not) or in scalar form, either quantitative (e.g., from zero to ten) or qualitative (e.g., beginner, intermediate, expert).
- Interests can represent news, web pages, documents, work-related or hobbies-related topics that can be classified as short-term or long-term interests. These interests can be stored in several ways: through weighed vector of keywords (weights usually represent the relevance of each keyword), topic hierarchies (each node in the hierarchy represents a topic of interest, defined by a set of representative words) and topic ontology (an human-understandable, but machine-readable format).
- Goals and Tasks represent the immediate purpose or objective for a user's work within the system, usually being a learning goal in educational AH systems. The goal or task is almost always changing from session to session or even several times within one single session, being the most changeable user feature. Plan recognition is not trivial but it is a useful technique that helps discovering the user's intention by observing the set of input tasks and inferring the next (most probable) one and, hence, the user's goal. Goals or tasks can be represented in the user model with the same patterns of the knowledge, but also as a Bayesian network where nodes represent user tasks and arcs represent probabilistic dependencies between them.
- Background and Skills are a set of features related to the user's previous experience outside the core domain of the system (e.g., profession, work experience or language) and they are used most frequently for content adaptation. They are very similar to user's knowledge and they can be also stored as binary or scalar form, but their update is typically explicitly (requesting

users themselves or their superior – e.g., teacher, boss – to fulfill their background and skills).

- Behavior represents a repetitive pattern that can be used to assist the user. The modeled behavior type depends on the application domain: some systems help users to schedule their day (by learning rules and suggesting meetings based on them), buying things (by recording preferences) and learning (by recording the period of time that an action occurs), for instance.
- Interaction preferences refer to the users' interaction habits and preferences when they interact with an interface. The AH system should infer the preferred agent action (e.g., warning, suggestion or interruption of the work) and modality for different situations or contexts. For example, one student is creating a study group to review the content on Saturday, but another student involved probably will not attend because he never attended commitments on Saturday. Some students would prefer a simple warning, while others would want suggestions about an alternative date. To learn users' interaction preferences, the AH system must store information about the necessary situations and the intervention type.
- Individual traits define who the user is as an individual, including demographic information (e.g., sex, age, marital status, country, number of children), personality traits (e.g., introvert/extravert), cognitive styles (e.g., holist, serialist), cognitive factors (e.g., working memory capacity) and learning styles.
- Context involves any information that can be used to characterize the person, place or object which is relevant to the interaction between the user and the AH system, including the user and the system themselves. Context-aware systems provide rel-

evant information based on the context and the adaptation is guided by the user needs.

The process of acquiring information to fulfill the user model involves capturing the appropriate data, selecting the relevant information and interpreting the user interactions activities (Koch, 2001). This acquisition can be explicitly (through the input of data via forms provided for this purpose) or implicitly (observing actions). The problem of explicitly acquisition is that users are not willing to fill in long forms providing information about them and, if they do, it may not be the truth about them (intentionally or deliberately). Based on data stored in the user model, the AH system can perform the adaptation with many different methods and techniques.

METHODS AND TECHNIQUES

Many techniques and methods can be used to adapt hypermedia systems. While techniques are a part of the implementation level (being characterized by a specific kind of knowledge representation and by a specific adaptation algorithm), methods are part of the contextual level (being generalizations of one or more techniques) (Brusilovsky, 1996). This section describes some existing methods and techniques divided into three levels: content, presentation and navigation.

Content Adaptation

Content level enables the AH system to modify content, showing basic or detailed information about a topic according to users' knowledge, for example. The content adaptation aims to increase the system usability for a group of users with different knowledge, background and goals. This adaptation consists essentially in providing additional, comparative or alternative content, also hiding the irrelevant parts of content for each user (Gasparini, 2003). Content adaptation methods

can be divided into: Additional Content, Explanation Variant and Sorting, described below based on Brusilovsky (1996) and Kobsa et al. (2001).

- **Additional Content:** Shows only the relevant fragments based on goals, interests, preferences or levels of knowledge of each user. It is the most widely used method to adapt the content, being divided into:
 - **Additional Explanation:** Hides irrelevant fragments to the current level of knowledge of the user (i.e., inability to understand) or in agreement with user interest.
 - **Prerequisite Explanation:** Modifies the fragments based on prerequisites among related concepts and on user's knowledge. AH system considers that the user knows about the related concepts (i.e., prerequisites) if the user has already accessed each one.
 - **Comparative Explanation:** Presents a comparative explanation (defining similarities and differences) between the presented concept and related ones. This method is based on similarity links between concepts.
- **Explanation Variant or Variant Content:** Stores variants of the fragments and shows only the ones considered more appropriate for each user. This method is usually used when showing or hiding fragments is not enough, since users may need information fundamentally different.
- **Sorting:** Places the fragments in a hierarchical order and the most relevant fragments are displayed first, based on the user's background and knowledge.

Content adaptation techniques are described below based on Brusilovsky (1996), Kobsa et al. (2001) and Knutov et al. (2009):

- **Conditional Text:** Divides all information into fragments and each fragment is associated with one or more conditions repre-

sented in the user model (if conditions are satisfied, the content is presented). This is used to implement the Additional Content and Explanation Variant methods.

- **Adaptive Stretchtext:** Shows or hides all fragments related with a specific "hotword". It replaces the hotword with the fragments if they are important and relevant, based on the user's knowledge and preferences. Otherwise, fragments will be collapsed and the user will only see the hotword. This technique is used to implement the Additional Content method.
- **Page Variant:** Stores two or more variants of a page to present differently the same concept. This technique is used to implement the Explanation Variant method.
- **Fragment Variant:** Stores two or more variants of a fragment to be combined during the presentation of a single page, in a way that best suits the user model. This technique is considered more complex to implement than the Page Variant technique, since the page needs to be dynamically created with the predefined fragments. This technique is used to implement the Additional Content and Explanation Variant methods.
- **Fragment Coloring:** Presents the same content while highlights the fragments of information according to their classification (e.g., very relevant, relevant, less relevant and irrelevant) for each user. This technique is used when all users must view the same content (sorting method) because it has a relatively low adaptation.
- **Frame-Based Approach:** Represents all information about a particular concept in form of a frame. These slots of a frame can contain several explanation variants of the concept, links to other frames and examples that are shown, hidden and reordered based on the user model. This technique is used to implement the Additional Content, Explanation Variant and Sorting methods.

Presentation Adaptation

Presentation level enables the AH system to present more or less navigational functionalities based on user's knowledge, background and skills. The presentation adaptation aims to increase the system usability for users, by making a visual change (layout) or textual change (language) (Gasparini, 2003). Presentation adaptation methods can be divided into: Multi-language and Layout Variant, described below based on Koch (2001).

- **Multi-Language:** Changes the system language according to the user's preference, which may also depend on the context.
- **Layout Variant:** Creates several alternatives for required items of interface: color, font size, font style, size, maximum image size, text orientation.

Presentation adaptation techniques to implement the presentation adaptation methods are almost the same techniques used for adapt the content, except for the adaptive stretchtext and the fragment coloring. The Conditional Text, Page Variant, Fragment Variant and Frame-based Approach techniques can be used to implement Multi-language and Layout Variant methods. Beyond these techniques, there is the Styleguiding technique, which defines different styleguides for the same page, to implement the Layout Variant method (Koch, 2001).

Navigation Adaptation

Adaptive navigation helps users to find their paths in hyperspace by modifying the presentation of links (Brusilovsky, 1996). A link is a visible and "clickable" representation of related pages for which the user can navigate, being classified by its kind: Local Non-contextual Links, Contextual Links, Links from Index or Content Pages and Links on Local or Global Hyperspace Maps.

Navigation adaptation methods can be divided into: Local Guidance, Global Guidance, Local Orientation, Global Orientation and Personalized Views, described below based on Brusilovsky (1996).

- **Local Guidance:** Helps users to continue the navigation, suggesting the best link(s) from the current page, based on users' preferences, knowledge and background.
- **Global Guidance:** Helps users to find the shortest path to get to what they are looking for, through the suggestion of the most appropriate links from the current page, for example.
- **Local Orientation:** Helps users to understand the different possibilities of navigation and to follow the most appropriate link from a given position.
- **Global Orientation:** Helps users to understand the structure of the entire hyperspace and their position within this structure.
- **Personalized Views:** Generates and updates the hyperspace with a personalized view for the user, building a working interface in a personalized way through adaptation.

Navigation adaptation techniques can be divided into: Direct Guidance, Sorting of Links, Link Hiding, Link Removal, Link Disabling, Link Annotation and Map Adaptation, described below based on Brusilovsky (1996), De Bra & Calvi (1998) and Knutov et al. (2009).

- **Direct Guidance:** Chooses the best page to continue the navigation. This is the most flexible technique, since it is possible to recommend a link that is not directly related to the actual one.
- **Sorting of Links:** Classifies and orders the available links, placing the most relevant links first. Its usage can reduce the naviga-

tion time, but it also can confuse users who reminds the link location, since the AH system reorders the links on each access.

- **Link Hiding:** Restricts the navigation by hiding irrelevant links. This is one of the most used techniques to adapt the navigation because it can be used with all kinds of links described above, besides reducing the workload of the user.
- **Link Removal:** Restricts the navigation by removing irrelevant links, instead of hiding them. This technique is usually combined with the Sorting of Links technique, which defines the most relevant links to be shown while the others are removed.
- **Link Disabling:** Restricts the navigation by disabling the functionality irrelevant links (i.e., removing anchors of links). In this case, the link is still visible to the user, but clicking on it will have no effect.
- **Link Annotation:** Adds comments to the link, allowing users to know more about its actual state. This comment can be textual or visual (using icons, colors or different font size) and it can classify links in several ways (e.g., visited/not visited, very relevant/relevant/irrelevant, not ready to be learned/ready to be learned/learning/learned) instead of only two (relevant/not relevant).
- **Map Adaptation:** Is a combination of all other techniques listed above, being applied to a graphical presentation of the navigational structure (i.e., map). It can be used to adapt the map without changing its structure, while reducing the browsing space by elimination anchors and guiding users in order to prevent them to get lost in the hyperspace.

There are several applications that use these methods and techniques to perform the adaptation of the system, described in the following section.

APPLICATIONS

Focusing on Educational Hypermedia, one of the first web-based AH systems created was the ELM-ART (acronym for ELM-Adaptive Remote Training), which was originally implemented to help students in learning LISP programming language (Brusilovsky et al., 1996). Even with the positive results of several empirical studies, ELM-ART approach received few expansions since its original version had many limitations (e.g., it can only focus on beginners due the high complexity of advanced concepts compared with the benefits of the possible learning support and it allows only the authors to add new content and activities) (Weber & Brusilovsky, 2015). Another Educational AH system is Interbook, created as an attempt to refine and improve some features of ELM-ART. Interbook uses users' knowledge to provide adaptive guidance (via direct guidance) and adaptive navigation (via link annotation) (Brusilovsky et al., 1998).

One of the most famous AH system is AHA! (Adaptive Hypermedia Architecture), which is an open-source and web-based system originally created for educational area (De Bra et al., 2006) that likewise distilled some of the ELM-ART limitations. AHA! uses the AHAM reference model and some methods to adapt its content (e.g., additional content) and presentation (e.g., layout variant), in addition to some techniques to adapt the navigation (e.g., link hiding, link removal and link annotation) (De Bra & Calvi, 1998) (De Bra et al., 2003).

The AdaptWeb® system is an Educational AH system focused on distance education. The AdaptWeb® architecture is based on four modules: authoring, storage, content adaptation and adaptive interface modules. The authoring module structures and organizes the instructional content via an authoring tool (creating a structure of concepts, establishing prerequisites criteria and associating files, examples, exercises and complementary ma-

terials for each the concept). The storage module receives this structure and stores data in an XML file, which serves as a basis to generate files for the adaptation modules. The content adaptation and adaptive interface modules work together, adapting the content, presentation and navigation through the XML generated and the user model (De Oliveira et al., 2003). Based on user's educational level, AdaptWeb® applies some techniques such as fragment variants to adapt content and direct guidance and link removal, disabling and annotation to adapt navigation. Based on user's working environment, AdaptWeb® adapts content using conditional text technique and, based on user's knowledge, it adapts the navigation using link disabling and annotation techniques. AdaptWeb® has been constantly updated and improved. Recently, the system incorporated a recommender system, learning analytics and gamification techniques, which are some of the trends and future research directions described in the next section.

FUTURE RESEARCH DIRECTIONS

Although it is not a new area, many trends have been explored in recent years. A study conducted by Somyürek (2015) raised some of these trends, divided into seven categories: standardization, semantic web, modular frameworks, data mining, machine learning techniques, social web and device adaptation. Here we describe some of these trends described by (Somyürek 2015) and we identified another: gamification.

Standardization aims to develop a set of interoperable, reusable and accessible resources, besides facilitating the management of them in the educational context. Standardization in AH systems usually occurs at the metadata level, which are ways of describing learning objects and user model to enable the integration with other AH systems (Fischer, 2001). Some metadata standards currently used are: Dublin Core, IMS Learning Resource Metadata and IEEE Learning Object Metadata (LOM).

Data mining is used to construct an understandable structure by means of analyzing large quantities of data, being divided into clustering and classification. Clustering assigns students with similar characteristics in the same group, while classification determines which these characteristics are (e.g., interests, skills, cognitive and learning styles). These data are usually used to recommend learning objects more effectively to each characteristic or even to implement a recommender system (Somyürek, 2015).

Social web has become very popular in recent years since knowledge has become more personal, social, distributed and dynamic by nature. In addition, mobile devices (e.g., laptops, smartphones and tablets) are becoming increasingly available and, therefore, they can be used for educational purposes. Because of that, device adaptation is necessary to provide a better presentation of the content based on the students' devices and, also, on their skills (Somyürek, 2015). In this sense, the work of (Machado & Oliveira, 2014) proposes the adaptation and resource recommendation for students using mobile devices.

Gamification is a new approach that can be used to motivate and engage students with game elements and design in non-game contexts (Deterding et al., 2011). In the educational area, there are many initiatives involving the use of gamification (e.g., (Grant & Betts, 2013), (Ibanezet al., 2014) and (Hanus & Fox, 2015)). Although the theme is new, there are already initiatives in order to unite the AH systems and gamification, as the work of (Klock et al., 2015). This work is in development and aims to perform the adaptation of gamification based on the characteristics of the students, since not all students will be motivated by the same game elements.

CONCLUSION

Adaptive Hypermedia (AH) systems are able to adjust their status in accordance with the users' profile, behavior and context (Gasparini, 2013),

building a user model with various information about user characteristics, such as: skills, knowledge, needs, preferences, behavior, way of interaction with the system, etc. AH systems bring a new perspective and they can improve the user interaction with computer systems (Gasparini, 2013), being also an alternative to one-size-fits-all approach and, since they allow different students to use the same form of environment adapted to their profile, being useful in educational area.

Through the adaptation of hypermedia systems, it is possible to know the characteristics of students and facilitate a learning process centered on the user. In this chapter, it was exposed some techniques and methods used for adaptation and identified some of the main characteristics of students considered for such adaptation. Thus, it is possible to visualize the importance of AH systems when we analyze the students' learning difficulties. This area is expanding and it presents various trends such as standardization, data mining, social web, device adaptation and gamification.

KEY TERMS AND DEFINITIONS

Adaptable Hypermedia System: A hypermedia system that allows the user to customize its preferences in a non-automatic way.

Contextual Links or Real Hypertext Links: Links that can be embedded in the context of the page (e.g., using “hotwords” in texts, “hot spots” in images), but they cannot be removed. They are not easy to manipulate as the local non-contextual links.

Links from Index or Content Pages: Appear on pages that contain only links presented in a fixed order (by alphabetical order for index pages and by content for content pages). These links are usually easy to manipulate, unless the page is implemented as an image.

Links on Local or Global Hyperspace

Maps: Appear on maps that represent a local area or even an entire hyperspace as a network of nodes connected by arrows. Using these maps, users can directly navigate to all visible nodes just by clicking on the representation of the desired node.

Local Non-Contextual Links: Are links independent from the content, being easy to manipulate and appearing as a set of buttons, links or a pop-up menu.

Group Synchronization for Multimedia Systems

Dimitris N. Kanellopoulos
University of Patras, Greece

INTRODUCTION

An important feature of multimedia applications is the integration of multiple media streams that have to be presented in a synchronized fashion (Li *et al.*, 1997). Synchronization is mainly the preservation of the temporal constraints within and among multimedia data streams at the time of playout. Temporal relations define the temporal dependencies between media objects (Blakowski & Steinmetz, 1996). An example of a temporal relation is the relation between a video and an audio object that are recorded during a concert. If these objects are presented, the temporal relation during the presentations of the two media objects must correspond to the temporal relation at the time of recording. Discrete media like text, graphics, and images are time-independent media objects, while the semantic of their respective content does not depend upon a presentation to the time domain. A discrete media object is frequently presented using one presentation unit. On the contrary, a time-dependent media object is presented as a media stream. In a continuous media stream (e.g. video), the presentation durations of all units of a time-dependent media object are equal (Li *et al.*, 1997). For example, a video consists of a number of ordered frames. Each of these frames has fixed presentation duration.

Most of the components of a multimedia system support and address temporal synchronization. These components include the operating system, communication subsystem, databases, documents and even applications. In distributed multimedia systems, networks introduce random delays in the delivery of multimedia information, and there

are four sources of asynchrony that can disrupt synchronization (Akyildiz & Yen, 1996):

- Delay Jitter and Local Clock Drift.
- Different Initial Collection Times. Let us consider two media sources, one providing voice and the other video. If these sources start to collect their media units (MUs) at different times, the playback of the MUs of voice and video from the two sources at the receiver loses semantic meaning.
- Different Initial Playback Times. If the initial playback times are different for each user, then asynchrony will arise.

To ensure synchronized delivery of multimedia information, intelligent synchronization protocols/techniques are required. This article illustrates various issues on intra- and inter-media synchronization and presents the basic schemes for inter-destination media synchronization (IDMS). It presents IDMS standardization efforts and novel solutions for new multimedia applications. Finally, it outlines future research directions for IDMS.

BACKGROUND

Intra-Media Synchronization

Intra-media synchronization refers to the time relations between the presentation units of one time-dependent media object. An example is the time relations between the single frames of a video sequence. The spacing between subsequent frames is dictated by the frame production rate. Jitter

may destroy the temporal relationships between periodically transmitted MUs that constitute a real-time media stream, thus hindering the comprehension of the stream. *Playout adaptation algorithms* undertake the labor of the temporal reconstruction of the stream, which is referred to as the *restoration of its intra-stream synchronization quality* (Park & Choi, 1996). *Adaptive media playout* (AMP) improves the media synchronization quality of streaming applications by regulating the playout time interval among MUs at a receiver. To mitigate the effect of the jitter, MUs have to be delayed at the receiver in order a continuous synchronized presentation can be guaranteed. Therefore, MUs have to be stored in a buffer and the size of this buffer will correspond to the amount of jitter in the network. As the synchronization requirements can vary according to the multimedia application on hand, we must control the individual synchronization (delay sensitivity, error tolerance etc.) for each media separately. To this direction, Park and Choi (1996) investigated an efficient multimedia synchronization method that can be applied at intra-media synchronization in a consistent manner. They proposed an adaptive synchronization scheme, based on the delay offset and playout rate adjustment that can match the application's varying synchronization requirements effectively. Park and Kim (2008) introduced an AMP scheme based on a discontinuity model for intra-media synchronization of video applications over the best-effort networks. They analyzed the temporal distortion (i.e., discontinuity) cases, such as playout pause and skip, to define a unified discontinuity model. Finally, Laoutaris and Stavrakakis (2002) surveyed the work in the area of playout adaptation.

Inter-Media Synchronization

Inter-media synchronization refers to the synchronization between media objects of a multimedia object. An example of inter-media synchronization is the *Lip Synchronization* that refers to the temporal relationship between an audio and video stream for the particular case of human speak-

ing (Aggarwal & Jindal, 2008). There are many systematic specification methods to describe synchronization problems. Blakowski and Steinmetz (1996) illustrated the main synchronization specification methods: interval-based specifications, control flow-based specification, axes-based synchronization, event-based synchronization, scripts, and comments. A *Synchronization Specification* of a multimedia object can describe all temporal dependencies of the included objects in a multimedia object. It is comprised of:

- Intra-object synchronization specifications for the media objects of the presentation.
- Quality of Service (QoS) descriptions for intra-object synchronization.
- Inter-object synchronization specifications for media objects of the presentation.
- QoS descriptions for inter-object synchronization.

To achieve inter-media synchronization various algorithms have been applied. There are several types of synchronization control such as *Skipping* (Ishibashi et al., 2002a), *Buffering* (Ishibashi et al., 2002a), *Adaptive Buffer Control* (ABC) (Wongwirat & Ohara, 2006), *Queue Monitoring* (QM) (Hikichi et al., 2002), *Virtual-Time Rendering* (VTR) (Ishibashi et al., 2002b), and *media adaptive buffering* (Isomura et al., 2011). Boronat et al. (2009) have reviewed the most powerful inter-media synchronization algorithms. The building blocks of these algorithms are the synchronization techniques utilized both at the sender and receiver sides. These algorithms can use multiple of synchronization techniques to achieve the synchronization mechanism even from different categories (Din & Bulterman, 2012).

Classification of Inter-Media Techniques

Synchronization techniques can be categorized according to the '*location*', '*purpose*', '*content*', and '*information used*' (Boronat et al., 2009).

- Location of Synchronization Technique:**
 The synchronization control can be performed either by source or receiver. If control is performed by the source, most of the time it will require some feedback information from the receiver. The receiver will tell the source about the degree of asynchrony at the current instance.
- Live vs. Synthetic Synchronization (Type of Media):** In *live* media, the temporal relations are exactly reproduced at a presentation, as they existed during the capture process. Synthetic synchronization techniques are used for *stored* media.
- Information Used for Synchronization Technique:** The information included in the MU can be different like timestamp, sequence number. Some techniques use either sequence number or timestamp, while others may use both.
- Purpose of Synchronization Technique:**
 The techniques can be divided into four subcategories with respect to its purpose:
 - The basic control techniques, which are required in almost all the algorithms. Examples are the attachment of synchronization information in MUs at source and buffering of MUs at receiver.
 - The common control techniques, which can be applied in both ways.
 - The preventive control techniques, which are used to prevent the asynchrony in the streams.
 - The reactive control (or corrective) techniques are designed to recover synchronization in the presence of synchronization errors.

Table 1 shows a classification of inter-media techniques, based on the above criteria.

Table 1. Classification of inter-media techniques

Technique	Location	Description
Basic Control	Source control	Add information useful for synchronization: timestamps, sequence numbers (identifiers), event information and/or source identifiers.
	Receiver control	Buffering techniques
Common Control	Source control	- Skip or pause MUs in the transmission process. - Advance the transmission timing dynamically. - Adjust the input rate. - Media Scaling.
	Receiver control	- Adjust the playout rate. - Data interpolation.
Preventive Control	Source control	- Initial playout instant calculation. - Deadline-based transmission scheduling. - Interleave MUs of different media streams in only one transport stream.
	Receiver control	- Preventive skips of MUs (e.g. discardings) and/or preventive pauses of MUs (repetitions, insertions or stops). - Change the buffering waiting time of the MUs. - Enlarge or shorten the silence periods of the streams.
Reactive Control	Source control	- Adjust the transmission timing. - Decrease the media streams transmitted. - Drop low-priority MUs.
	Receiver control	- Reactive skips (eliminations or discardings) and/or reactive pauses (repetitions, insertions or stops). - Make playout duration extensions or reductions (playout rate adjustments). - Use of a virtual time with contractions or expansions. - Master/slave scheme - Late event discarding (Event-based). - Rollback techniques (Event-based)

MAIN FOCUS OF THE ARTICLE

Group or inter-destination media synchronization (IDMS) addresses the presentation of a stream at all the receivers of a group, simultaneously. For example, in real-time distance learning, tutor multicasts a multimedia lesson to a group of students located at different areas. The levels of required synchrony among the receivers depend on the application on hand. Akyildiz and Yen (1996) introduced group synchronization protocols for real-time, multimedia applications, including teleconference and multimedia on demand services. Their protocols achieve synchronization for all configurations (one-to-one, one-to-many, many-to-one, and many-to-many), and do so without prior knowledge of the end-to-end delay distribution, or the distribution of the clock drift. The only a-priori knowledge the protocols require is an upper bound on the end-to-end delay. Recently, Boronat *et al.* (2009) reviewed the most popular multimedia group and inter-stream synchronization approaches. Group synchronization techniques can be classified at three schemes. These schemes are based on the

Virtual-Time Rendering (VTR) media synchronization algorithm to determine the output timing of each MU, so that the timing can be the same at all the destinations. For better understanding of these schemes, consider that M sources and N destinations/receivers are connected through a network. MUs of M different streams have been stored with timestamps in M sources, and they are broadcasted to all the receivers. The timestamp contained in a MU indicates its generation time. The streams fall into a master stream and slave streams. At each receiver, for inter-media synchronization, the slave streams are synchronized with the master stream by using an inter-media synchronization mechanism.

Master/Slave Receiver Scheme (MSRS)

In MSRS (Ishibashi *et al.*, 1997), the receivers are categorized into one Master receiver and Slave receivers. Multiple streams are received at each receiver and one of these streams acts as master stream in order inter-media synchronization to be achieved at each receiver (Figure 1).

Figure 1. Master/slave receiver scheme
Sithu and Ishibashi, 2015.

None of the slave receivers send any feedback information about the timing of the playout processes. It adjusts the playout timing of MUs to that of the master receiver. Only the master receiver sends (multicasts) its playout timing to all the other (slave) receivers. The master receiver controls and computes the presentation time of the MUs according to its own state of the received stream data. Group synchronization is achieved by adjusting the presentation time of the MUs of master stream at the slave receivers to that of the master receiver. Therefore, the slave receivers should present MUs at the same timing as the master receiver. The synchronization of the slave receivers is achieved as follows:

- The master receiver multicasts a control packet to all slave receivers. This control packet includes the presentation time of its first MU of master stream. This process is called “initial presentation adjustment”.
- When the target presentation time of the master receiver changes, the master receiver notifies all the slaves about this modification by multicasting a control packet. This control packet contains the amount of time that is modified and the sequence number of the MU for which the target presentation time has been changed.
- The master receiver periodically multicasts proper control packets to accommodate the newly joined slave receivers.

Boronat *et al.* (2008) presented MSRS by extending the RTP/RTCP (Real-time Transport Protocol/RTP Control Protocol) messages for containing the synchronization information. Figure 1 presents the different type of message exchanges in the basic MSRS. The advantage of the MSRS technique is its simplicity and decreased amount of information exchange (i.e. control packets) to support group synchronization. However, the selection of the master receiver can influence the performance of the scheme. If the faster receiver is selected as the master receiver, it can cause the

Buffer underflow in the (slower) slave receivers, which can result as the poor presentation quality at slow receivers. On the contrary, if the slowest receiver is selected as master, it can cause *Buffer overflow* on fast slave receiver(s). This will result as high packet drops at faster slave receiver(s). A problem with the MSRS technique is that the master can act as a bottleneck in the system. A second problem deals with the associated degree of unfairness with the slave receivers. Boronat *et al.* (2011) discussed possible options with pros and cons for the master selection in this scheme.

Synchronization Maestro Scheme (SMS)

In SMS scheme, all the receivers are handled fairly as there are not master and slaves (Ishibashi & Tasaka 1997). SMS involves a *Synchronization Manager* (SM), which can be performed by one of the source or receiver. For example, in Figure 2, one receiver/destination performs the SM.

Each receiver estimates the network delay and uses the estimates to determine the local presentation time of the MU. Then, each receiver sends this estimated presentation time of MU to the SM. After that, the SM gathers the estimates from the receivers, and adjusts the presentation timing among the receivers by multicasting control packets to receivers. The SMS scheme assumes that clock speed at the sources and receivers is the same, and that the current local times are also the same (i.e., globally synchronized clocks). Figure 2 depicts the basic principle of the SMS technique. Boronat *et al.* (2009) presented the RTCP based schemes, which follow the same basic principle. The SMS scheme (like the MSRS) is a centralized solution, and thus it can confront the bottleneck problem. The advantage of the SMS scheme over MSRS is its fairness to the receivers, as the feedback information of all the receivers is accounted for determining the presentation time of the MU. However, this fairness costs more communication overhead among the receiver and the synchronization manager.

Figure 2. Synchronization maestro scheme
Sithu and Ishibashi, 2015.

Distributed Control Scheme (DCS)

Figure 3 illustrates the DCS scheme (Mauve *et al.*, 2004). Each receiver estimates the network delay, and then determines the presentation time of the MU. Then, it sends (multicasts) this presentation time to all the receivers. After that, every receiver will have the entire view of the estimated time of MU. Each receiver has the flexibility to decide the reference play out time among the timing of all the receivers. The DCS scheme provides higher flexibility to each receiver to decide the presentation time of MU. For example, it is possible that by selecting the presentation time of other receiver, it can achieve higher group synchronization quality, but it may cause the inter-media or intra-media synchronization degradation. In this case, the receiver has the flexibility to choose between the types of synchronization depending upon the nature of application on hand. If the application on hand requires the higher inter-media or intra-media synchronization and can sacrifice on the group synchronization to certain limit, then

receiver can select its own determined presentation time and vice versa. DCS is a distributed scheme by nature and does not suffer from the bottleneck problem. If one or more receivers leave the system, it will not disturb the overall scheme. This greater flexibility and the distributed nature of DCS make it complex in terms of processing. This happens because the receiver does more calculations and comparisons before deciding the presentation time of MU. Finally, DCS has higher message complexity, as each receiver multicasts the estimated presentation time.

SOLUTIONS AND RECOMMENDATIONS

Standardization of IDMS has been carried out within ETSI (European Telecommunications Standards Institute) TISPAN (Telecoms & Internet converged Services & Protocols for Advanced Networking). In addition, such standardization is a highlight for the IETF AVTCORE WG (In-

Figure 3. Distributed control scheme
Sithu and Ishibashi, 2015.

Internet Engineering Task Force - Audio/Video Transport Core Maintenance Working Group). The specification (ETSI, 2009) does pose IDMS and the synchronization of media streams from different sources as a requirement for providing synchronization-sensitive interactive services. These use cases are mostly in the categories of low or medium synchronization, and not very high requirements are posed to delay differences between various user equipments. The protocol specification gives a delay difference of between 150 and 400 ms as a guideline for achieving transparent interactivity, based on ITU guidelines for interactivity in person-to-person communication. ETSI TISPAN has done the first work on standardizing RTCP usage for IDMS. The ETSI proposal is a dedicated solution for use in large-scale IPTV deployments, with low to medium level synchronization requirements. Other services such as Internet-based video services may also benefit from IDMS, and other use cases require higher levels of synchronization, and are not supported by

the ETSI solution (Montagud et al., 2012). Within the Internet Engineering Task Force (IETF), the AVTCORE working group (Brandenburg et al., 2012) carries out standardization of the RTCP-based IDMS protocol. This is the core group that is responsible for the RTP and accompanying RTCP protocol. Most RTCP extensions are developed within the IETF. Boronat et al. (2009) described most IDMS solutions that define new proprietary protocols, with specific control messages, that should increase the network load. Montagud et al. (2012) presented up to 19 use cases for IDMS, each one having its own synchronization requirements.

Presentation adaptation and flow control is a feasible solution to achieve a smooth multiple-stream distributed multimedia presentation. Huang et al. (2001) proposed the *Pause-And-Run* approach for k -stream (PARK) multimedia presentations over Internet to achieve reliable transmission of continuous media. They evaluated the application of the PARK approach over the Internet. The evaluation results revealed a suitable

buffering control policy for the audio and video media, respectively. The characteristics of the PARK approach are:

- PARK adopts TCP to achieve reliable transmission for continuous media.
- A novel flow adaptation scheme is proposed to reduce the overhead of the network and end-hosts as the slow-start scheme is embedded in TCP. The server adapts its transmission rates to the buffer situation of the client and prevents the client's buffers from overflow and underflow as much as possible.
- With the provision of multiple-stream synchronization and the multi-level adaptation control, the client achieves smooth multimedia presentations and graceful presentation degradation.

Realization of *Synchronous shared experiences* requires that users feel that they are *coherently* communicating with each other. Vaishnavi *et al.* (2011) analyzed challenges that need to be tackled to achieve coherence: *Quality of service, mobility and distributed media synchronization*. They presented their solution to distributed media synchronization. Their design uses the local lag mechanism over a distributed control or master-slave signaling architecture. Montagud and Boronat (2012) presented an evolved version of an RTCP-based IDMS approach, including an AMP scheme that adjusts the play-out timing of each one of the geographically distributed consumers in a specific cluster, if an allowable asynchrony threshold between their play-out states is exceeded. Montagud *et al.* (2014) presented an IDMS solution based on extending the capabilities of RTP/RTCP protocols. To enable an adaptive, highly accurate and standard compliant IDMS solution, they specified RTCP extensions, in combination with several control algorithms and adjustment techniques. Montagud *et al.* (2015) reviewed the existing sync reference models by examining the involved features, components and layers in

each one of them. Their study reflects the need for a new modular and extensible theoretical framework to efficiently comprehend the overall media sync research area. Belda *et al.* (2015) presented *Wersync*, a web-based platform that enables distributed media synchronization and social interaction across remote users. Costa and Santos (2014) surveyed the existing media sync solutions focused on the TV area, classifying them in terms of: types of involved devices, types of media content, types of sync techniques, targeted applications or scenarios, and evaluation methodologies.

Ishibashi *et al.* (2014) carried out QoE (Quality of Experience) assessment of fairness between players in a networked game with olfaction. They investigated the influence of the time it takes for a smell to reach a player on the fairness. They illustrated that the fairness is hardly damaged when the constant delays are smaller than about 500 ms. The used media synchronization algorithm considers the human perception of intra-stream and inter-stream synchronization errors. Ghinea and Ademoye (2010) conducted a perceptual measurement of the impact of a synchronization error between smell sensory data and audiovisual content, assuming the audiovisual lip skew is zero. Their results show a synchronization threshold of 30 s, when olfaction is ahead of audiovisual data, and of 20 s when olfaction is behind.

In *joint musical performance*, multiple users play their respective same or different types of musical instruments together, but the media synchronization quality and interactivity may seriously be deteriorated owing to the network delay. Sithu and Ishibashi (2015) proposed a new media synchronization control called the '*dynamic local lag control*'. By QoE assessment, they demonstrated that the new control can achieve high quality of media synchronization and keep the interactivity high.

Huang *et al.* (2013) have presented a historical view of temporal synchronization studies focusing on continuous multimedia. They demonstrated how the development of multimedia systems has

created new challenges for synchronization technologies. They concluded with a new application-dependent, multi-location, multi-requirement synchronization framework to address these new challenges.

FUTURE RESEARCH DIRECTIONS

Group synchronization techniques could benefit from the cross-layer optimization. Cross-layer optimization allows communication between OSI RM layers by permitting one layer to access the data of another layer to exchange information and enable interaction (Bin-Salem & Wan, 2012). It contributes to an improvement of quality of services under various operational conditions. The cross-layer control mechanism provides a feedback on concurrent quality information for the adaptive setting of control parameters of a multimedia system. Thus, it can help to the utilization of synchronization techniques (e.g. preventive control techniques). Soon, researchers will develop more comprehensive multimedia synchronization subsystems that will integrate preventive and reactive methods and will take into account the cross layer optimization and other components (the operating system, communication subsystem, databases, documents and applications). Such systems must be able not only to achieve intra- and inter-media synchronization, but also the IDMS to a diversity of new multimedia applications.

In RTP-based multimedia streaming services, client-driven media synchronization mechanisms must be developed to provide accurate media synchronization such as to reduce: the initial synchronization delay, the processing complexity at the client device, the number of required user datagram protocol ports, and the amount of control traffic injected into the network. Such a synchronization mechanism was recently proposed by Jung and Seo (2016). In their method, the server does not need to send any RTCP SR packets for synchronization. Instead, the client

device derives the precise normal play time for each video and audio stream from the received RTP packets containing an RTP timestamp.

CONCLUSION

This article has illustrated various issues on intra and inter-media synchronization. It has presented basic schemes of IDMS and has mentioned IDMS standardization efforts and novel solutions for new multimedia applications. Also, it has outlined future research directions on IDMS. Certainly, standardization of IDMS will facilitate the uptake of implementations and of the interoperability between different implementations, ensuring a more extensive use of IDMS. Interactive 3D tele-immersive applications are future applications that can provide geographically distributed users with a realistic and immersive multimedia experience. Such applications can lead to new requirements for synchronization, and thus novel multidimensional synchronization models for next-generation multimedia environments must be proposed. There is also a strong demand to describe the impact of future application heterogeneity on human synchronization perception.

KEY TERMS AND DEFINITIONS

Delay Jitter: The variation of end-to-end delay; an inherent characteristic of best-effort networks.

Preventive Control Techniques: They used to prevent the asynchrony in the media streams. They minimize latencies and jitters and involve disk-reading scheduling algorithms, network transport protocols, operating systems, and synchronization schedulers.

Quality of Experience (QoE): A measure of a customer's experiences with a service (e.g. IPTV).

Reactive Control Techniques: These techniques are designed to recover synchronization in the presence of synchronization errors.

Scripts: A synchronization specification method that describes synchronization scenarios in multimedia objects.

Synchronous Shared Experiences: New social multimedia applications and services wherein

groups of users in different locations can watch multimedia content, while synchronously communicating with each other.

Synthetic Synchronization: Such synchronization is used in presentation and retrieval-based systems with stored data objects that are arranged to provide new multimedia objects. The temporal relations have been artificially assigned to media that were created independently of each other.

Virtual-Time Rendering (VTR) Algorithm: A popular intra- and inter-stream synchronization algorithm applicable to networks with unknown delay bounds. It makes use of globally synchronized clocks, and consists of the dynamic adjustment of the MUs rendering-time, according to the network condition.

Metadata Standards in Digital Audio

M**Kimmy Szeto***Baruch College, City University of New York, USA*

INTRODUCTION

Audio metadata are an essential tool that supports control and management of systems that create, transmit, describe, manage, and store digital audio. Throughout the lifecycle of digital audio objects—pre-production, acquisition and production, post-production, distribution, storage, transmission, and archiving—metadata “describe the attributes of a resource, characterize resource relationships, and support resource discovery, management, and effective use” (Vellucci, 1999). Technical and structural metadata enable audio in devices and software applications; descriptive metadata provide context. Metadata also relate and incorporate audio in a multimedia environment resulting in profound effects on conception, reception, and consumption.

Issues of audio metadata are intertwined with audio equipment, music production, and information technology. Holmes (2006) gives a broad overview of the technology; Gilmer (2004) provides the background for usage in multimedia production; Lu & Hanjalic (2009) and Kriechbaum (2009) detail the technical aspects in database systems; Casey & Gordon (2007) offer the information professional perspective. International audio metadata standards are chiefly issued by the European Broadcasting Union (EBU), the Society of Motion Picture and Television Engineers (SMPTE), and the Audio Engineering Society (AES). Guidelines for usage and implementation are routinely published by these three organizations, as well as by manufacturers, libraries, and archives.

BACKGROUND

Analog sound recording technologies had been in use for over a century when the Compact Disc Digital Audio (CD-DA) technology emerged in the late 1970s following breakthroughs in signal processing and the optical medium. Audio continued to be produced in a mixture of analog and digital systems consisting of single-purpose devices designed for recording and producing audio to be transmitted in either analog or digital form. The production system was largely determined by the transmission medium—wire, wax cylinder, shellac disc, vinyl disc, magnetic tape, broadcast, optical disc—each requiring an assortment of specialty equipment, typically supplied by a single manufacturer. In such vertically integrated systems, controls and switches that supplied parameters and characteristics (metadata) to the audio were generally integrated in the hardware. Where metadata were specified and shared, the necessity for interoperability was limited to the devices immediately before and after in the production chain.

As digital signal processing technologies evolved, the proliferation of recording formats, compression methods, and media formats made it no longer sensible to build a separate integrated system for each device combination. In such a mixed production environment, devices need to be able to pass along and recognize standardized metadata throughout the production process. For several decades since the 1970s, the broadcast industry attempted to standardize metadata within device categories to allow for interchangeable equipment for each step of the production. But

demands for higher flexibility and broader scope mounted as increasing prevalence of computer software and data networks shifted production workflow and transmission toward a distributed model. The industry was compelled to re-conceive use of metadata in not only audio, but also video production in a digital environment where data and content would be stored and transmitted in the form of computer files. These files, ideally, would encapsulate all necessary metadata, interoperable through the production chain, regardless of media format or equipment.

EBU and SMPTE established the Task Force for Harmonized Standards for the Exchange of Program Material as Bit Streams in 1995 to study the long-term interoperability and stability of production systems. In its 1997 report, the Task Force elevated metadata to be equal in significance to the signals, casting the formulas “Content = Essence + Metadata” and “Asset = Content + Rights.” (Essence includes video, audio, and data; metadata represents information about the essence, including rights.) And, among other technical details, the Task Force, anticipating the need to store and transmit digital multimedia as computer files, specified the generalized file format, or “wrapper.” This format consists of three parts—the preamble, consisting solely of metadata, the body, containing the essence and additional metadata, and the end-of-file marker. The wrapper provided the means to link metadata and essence logically and physically. This structure allowed audio files to contain an ever-increasing variety of metadata. SMPTE published the Metadata Element Dictionary Structure (SMPTE 335:2012) and established the SMPTE Registration Authority (2010), a public metadata registry, to serve as a basis and the administrative body for the development of future metadata standards. Open standards will guide the development of audio and multimedia metadata standards to handle increasingly complex and horizontal system design. Global adoption of well-defined international standards will facilitate data exchange and re-use, as well

as guarantee long-term preservation and combat format obsolescence.

Efforts to standardize audio metadata also dramatically shaped the consumer experience and conception of audio. With analog audio, consumers’ ability to produce and manipulate audio was limited to using audiocassette systems. As the Sony Corporation introduced the Walkman, a portable cassette player, in 1979, listening became personalized. Later, personal portable players were extended to the Compact Disc medium, even though recording devices did not reach consumers until much later. With the advent of storing and transmitting audio as computer files, however, audio consumption was no long tied to specific media or carriers. Personal computers allowed manipulation of audio and the associated metadata, and distribution of audio files over data networks. Widespread integration between personal computers, data networks, and personal portable players spurred consumer demands for describing and organizing digital audio. Descriptive metadata standards evolved and expanded in scope alongside techniques to generate audio semantics and analyze consumer preferences and behaviors, resulting in the ability to create personalized and customizable audio collections.

EMBEDDED METADATA IN DIGITAL AUDIO FILE FORMATS

Pulse-Code Modulation

Pulse-code modulation (PCM) is a method of representing analog signals in digital binaries. It was first developed in 1937 by British engineer Alec H. Reeves for audio transmissions over telegraph. Reeves was granted patents in France in 1938, in Britain in 1939, and in the United States in 1942, but lacked the equipment to produce the digital audio efficiently (Deloraine & Reeves, 1965; Robertson, 2005). The digital coding of analog signals is accomplished in three steps. Sound signals are

sampled at specific time intervals (8,000 times per second for typical telephone speech; 44,100 for Compact Disc Digital Audio; up to 96,000 and beyond for high quality recordings). Then, the sampled signals are assigned values, or quantized. Finally, each of these values is represented in binary code. The uncompressed digital audio is called Linear PCM (LPCM), while compressed variants are variously called μ -law, A-law, differential PCM, adaptive differential PCM, etc., depending on technique and application. Today, with the widespread use of semiconductor equipment, PCM serves as the basis for virtually all forms of digital communications.

Compact Disc Digital Audio

Compact Disc Digital Audio is the standard format for audio on compact discs first released in 1980 by Koninklijke Philips and Sony in a publication commonly known as the Red Book. The Red Book specifies the maximum duration of a disc (79.8 minutes), tracks per disc (99), and index points per track (99), the minimum duration of a track (4 seconds), the use of the International Standard Recording Code (ISRC) (ISO 3901), and the audio format (2 channels of 16-bit LPCM sampled at 44.1 Hz). The Red Book standard was codified in 1987 in the International Electrotechnical Commission publication IEC 60908, and its second edition was published in 1999.

Several extensions to the Red Book specification have been introduced. CD-Text, introduced by Sony in 1996 as part of its Multimedia Command Set, provides the ability to store 4 megabytes of textual information about the audio contents such as album title, track title, and authors in the Interactive Text Transmission System (IEC 61866), which is also used for MiniDiscs and digital radio broadcasting. CD-Text has been widely adopted, and CD-Text metadata have been harvested and made available via online databases such as Gracenote (formerly Compact Disc Database, or CDDb) and freedb.

Compact Disc + Graphics (CD+G) was introduced by Philips and Sony in 1985 for storing low-resolution graphics for on-screen display during audio playback. This is an early specification involving storing images as metadata. CD+G and its later revision, Compact Disc + Extended Graphics (CD-EG) are chiefly used for interactive audio playback such as karaoke, but, while part of the Red Book standard, they are otherwise not widely adopted.

Interchange File Format

The Interchange File Format (IFF) (EA IFF 85), developed by Electronic Arts, was originally introduced in 1985 for graphic files in Commodore-Amiga systems, but it is a generic file format that can be used for a variety of media types, including audio. The IFF file consists of a sequence of chunks. Each chunk includes an area that declares the chunk, followed by an area that specifies size, and then the area for the data (known as Key-Length-Value encoding, or KLV), which may include other nested sub-chunks. The concepts of chunks, as well as the requirement for each chunk to provide metadata to self-identify and self-describe, lay the foundation for the basic audio file formats, including Audio Interchange File Format, developed by Apple Computer, and the Resource Interchange File Format, developed by the Microsoft Corporation and the International Business Machines Corporation (IBM), on which their Waveform Audio File Format is based.

Audio Interchange File Format

The Audio Interchange File Format (AIFF) is an audio application of IFF developed in 1988 by Apple. AIFF originally supported only uncompressed PCM audio; support for compressed audio was added in its 1991 revision, AIFF-C. Metadata elements specified in AIFF are listed in Table 1. AIFF requires technical metadata (Common Chunk) and the audio (Sound Data Chunk), while AIFF-C

requires an additional version number (Format Version Chunk). Other optional chunks include additional technical and descriptive metadata designed to provide machine-actionable capability (such as looping), user- and application-interactive features (such as commenting), and extensibility. The concept of time-stamped comments pegged to specific points in the audio data is widely applied today for versioning, subtitling, user tagging, and provenance tracking. Extensibility provided by the Application Specific Chunk allows applications to create custom metadata and incorporate external metadata for storing state parameters such as date last played, last stop position, and user ratings, additional descriptive metadata such as ID3 tags, as well as other binary files such as album cover art—all popular features of audio file management software today.

Resource Interchange File Format

The Resource Interchange File Format (RIFF) was introduced in 1991 by Microsoft and IBM. The format is identical to IFF except for the labeling of chunk names and endianness, the ordering of bytes within computer memory, which are opposite in the processors used in Apple and IBM computers. Microsoft, which develops software on IBM computers, has implemented several file formats based on RIFF, including the WAV, also introduced in 1991.

Waveform Audio File Format

Metadata elements specified in WAV are listed in Table 2. The functionalities offered by WAV are similar to those offered by AIFF/AIFF-C, and also allow custom-defined chunks to be included in the file. The latest addition to the WAV format, Wave Format Extensible, supports multichannel audio with additional technical data.

Table 1. Metadata elements specified in AIFF

Chunk (All Optional Unless Marked)	Comment
Format Version (AIFF-C only, required)	The version of the AIFF-C format.
Common (required)	Technical metadata: number of channels, number of sample frames, bits per sample, and sample rate. Compression type code and a human-readable compression type name were added to AIFF-C.
Instrument	Defines the basic parameters of the playback sound sampler, i.e. the “instrument” as well as looping of audio data segments.
Saxel (AIFF-C draft only)	Sound accelerator data for eliminating decompression artifacts when playback begins at a point other than the beginning of the audio data. This chunk was not officially adopted.
Comments	Free text that can be time-stamped and linked to a marker.
Marker	A marker points to a position in the audio data. It can be used by the Instrument Chunk, the Comments Chunk, or any other element in the Application Chunk.
Sound Data (required)	The audio data. Uncompressed LPCM in AIFF; in AIFF-C, the audio data can be compressed as defined in the Common Chunk.
Name	The name given to the audio.
Author	The creator of the audio.
Copyright	The copyright statement for the audio.
Annotation(s)	Free text, but using the Comments Chunk is preferred.
Audio Recording	Information that identifies the recording device (according to AES3: AES standard for digital audio - Digital input-output interfacing - Serial transmission format for two-channel linearly-represented digital audio data, section 7.1, channel status data).
MIDI Data (s)	Additional metadata included in the MIDI specification but not in the AIFF / AIFF-C.
Application Specific	Custom chunks created for any purpose by device or software application manufacturers.

Table 2. Metadata elements specified in the WAV format

Chunk (All Optional Unless Marked)	Description
Format (required)	Specifies the format, and technical metadata: number of channels, sampling rate, average sampling rate, and data block size.
Fact	Specifies the length of the audio.
Cue Points	Identifies a series of positions in the audio.
Playlist	Specifies the play order of a series of cue points.
Associated data list	Provides Label (title) and Note sub-chunks to be associated with a cue point; defines a Text with Data Length Information sub-chunk that associates a segment of the audio chunk with free text, purpose, country, language, and dialect.
Wave data	The audio data. Uncompressed LPCM or compressed as defined in the Format Chunk.
File	Contains data or metadata described in other file formats.
Instrument (added in the 1994 update)	Defines the basic parameters of the playback sound sampler, i.e. the “instrument”
Sample (added in the 1994 update)	Metadata for sampling keyboards to recognize the WAV audio as an instrument.

Broadcast Wave Format

The Broadcast Wave Format (BWF) is an extension of the WAV format. The BWF specification was first published by EBU in 1997 (EBU Tech 3285) as Version 0. Its Version 1, published in 2000, added support for the Unique Material Identifier in the SMPTE 330 standard, and was followed by 6 supplemental updates listed in Table 3, all of which were subsequently incorporated into the latest Version 2, published in 2011. BWF gained worldwide acceptance and has been incorporated into other file specifications such as MXF, AES57, and EBUCore/AES60. BWF restricts the audio coding to uncompressed LPCM and

Table 3. Supplements to BWF version 1

Supplement	Description
MPEG Audio	Specifies the additional technical metadata necessary to describe MPEG audio.
Capturing Report	Specifies additional information for the full transmission history of the analog-to-digital conversion and digital transfers, in order to safeguard the original quality of the audio.
Peak Envelope	Specifies additional information about peak audio signal levels in the file, in order to speed up opening, display, and processing.
Link	Provides a mechanism to link multiple BWF files for seamless output. Metadata is expressed in XML.
AXML	Formally defines the use of XML metadata in this BWF chunk.
Dolby	Specifies additional information associated with Dolby technologies, such as Dolby E, Digital and Dolby Digital Plus.

compressed MPEG and specifies an additional Broadcast Audio Extension Chunk (BEXT). The additional metadata facilitate exchange of audio files between computer platforms and applications, documentation of processing activities, as well as synchronization with other audio files. Table 4 lists BEXT metadata fields in BWF Version 2. Supplements of BWF specify additional metadata chunks for various applications. BWF has been extended to incorporate multichannel (MBWF) support of Wave Format Extensible. EBU also introduced RF64, which extended the definition of RIFF to support file size exceeding 4 gigabytes. The latest update in 2009 incorporates MBWF in R64 (EBU Tech 3306).

Other Digital Audio File Formats

Formats that have been developed for more specialized use and narrower functionalities include Sun Microcomputer’s AU format, Computerized Speech Labs’s NSP format, Entropic Research Laboratories’s ESPS and HTK formats, INRS

Table 4. BEXT metadata fields in BWF version 2

BEXT Data Field	Description
Description	A brief description of the audio.
Originator	Name of the producer of the audio.
Originator Reference	An identifier for the Originator, defined in EBU R 99.
Origination Date	Creation date of the audio.
Origination Time	Creation time of the audio.
Time Reference	Time code of the start of the audio.
Version	Version of BWF of the file.
UMID	Unique Material Identifier defined in SMPTE 330M.
Loudness Value	
Loudness Range	
Max True Level	
Max Momentary Loudness	
Max Short Term Loudness	
Reserved	Reserved for future extension.
Coding History	Record of the transmission chain—processing applied to the audio.

Telecom’s file format, IRCAM’s Soundfile format, and AT&T Bell Laboratories’s SPPACK format (Kabal, 2011).

Proliferation of digital audio and video on the Internet prompted rapid development of compressed audio and multimedia technologies. Some digital audio file formats have become known by their compression method, or codec, most notably the popular formats MP3, Advanced Audio Encoding (AAC), and Microsoft’s proprietary Windows Media Audio (WMA) format; some are subsumed under wrapper file formats designed for multimedia and streaming delivery, such as the MXF, Ogg, a series of MPEG standards, and Microsoft’s proprietary Advanced Systems Format. Consequently, the development of audio metadata diverged—technical metadata continue to be embedded within the audio file or specified as part of the multimedia file format, while descriptive metadata evolved independently to coordinate with these formats.

DESCRIPTIVE METADATA

ID3v1 and ID3v2

ID3v1 and ID3v2 are two related versions of metadata containers for descriptive metadata developed without a standardization body, but are standards in the de facto sense for their wide adoption by software applications and hardware manufacturers. The introduction of ID3 in 1996, now called ID3v1, is attributed to programmer Eric Kemp. A chunk of data was appended to the end of the MP3 file container to store descriptive metadata. The format was extended in 1997 to ID3v1.1, attributed to Michael Mutschler, which increased the storage size for the metadata (Nilsson, 2006). The ID3v1 chunk is 128 bytes long with fixed-length metadata tags for title, artist, album, year, comment, indicator for the use of the track number, track number, and genre code (listed in Table 6). The current standard ID3v2 provides an additional 227 bytes for extensions of title, artist, and album, as well as new tags for speed, genre (free text), and fading. In 1998, a group of developers introduced ID3v2 (Nilsson, 2012), which makes use of frames of variable size (up to 16 megabytes each and a total of 256 megabytes). The list of tags is shown in Table 5. In addition to textual metadata, ID3v2 allows for external URL links as well as embedding graphic images through the “APIC” frame.

The ID3v2 frame structure has been incorporated in AIFF, but not in WAV and BWF, although incorporation is possible by way of a custom ID3 Chunk. The set of ID3v2 tag names is also supported in WMA and the MPEG-4 (MP4) file formats, but the metadata are stored in a different data structure.

VorbisComments in Ogg

VorbisComments is a textual metadata specification for the open source Ogg file container format developed by the Xiph.org Foundation. Appeared in 2000, this specification is primarily concerned

Compiled from Harvey (2013) and Nilsson (1998, 1999, 2000b), and adapted from Solboda (2011).

with the structure and encoding. There is no mandatory field, and users are free to create any field. The Xiph.org Foundation recommends a “minimal list of standard field names” (listed in Table 7) and later added a mechanism for embedding digital images. Additional VorbisComments field names as well as other mechanisms for embedding descriptive metadata are being proposed, discussed, and tested by the user community.

Material Exchange Format

The Material Exchange Format (MXF) consists of a series of specifications published by SMPTE beginning in 2004. MXF grew out of the Advanced Authoring Format (AAF), and is a comprehensive file format that addresses the interoperability issue

in the production chain. The format is supported by EBU, the Association of Radio Industries and Businesses (ARIB), the Professional-MPEG Forum, the Advanced Authoring Format Association, as well as equipment manufacturers. The specifications focus on technical and structural metadata, and leaves open mechanisms for embedding descriptive metadata. Several recommended practices have been published (SMPTE 377-1, EBU R 121, SMPTE 380M). Although MXF metadata are KLV-encoded, mechanisms for incorporating XML metadata have been developed (EBU R 121, SMPTE 380M, SMPTE ST 434:2014). The *SMPTE Metadata Registries and Related Items* web site serves as a clearinghouse for metadata standards developed for MXF, including EBUCore.

Compiled from Harvey (2013), "Liste" (2013), and Strnad (2002).

0-79 were introduced with ID3v1; extended to 80-110 by the Winamp application in 1997; extended to 111-115, 116-141, 142-147 in 1998; extended to 148-191 in 2010; CR and RX values appear in ID3v2 only.

EBU and AES Metadata Specifications

The co-publication of EBUCore (EBU Tech 3293) in 2008 and AES60 (formerly AES-X098A) in 2011 was the result of the metadata harmonization project between EBU and the AES. EBUCore assumes the use of BWF, and, an extension of the Dublin Core metadata schema expressed in XML, was designed as a minimum list of elements for de-

scribing audio and video. The EBUCore metadata set includes 19 elements: Title, Creator, Subject, Description, Publisher, Contributor, Date, Type, Format, Identifier, Source, Language, Relation, Coverage, Rights, Version, Publication History, Metadata Provider, and Entity Type. EBUCore has been widely adopted by production and broadcasting organizations internationally. The EBUCore standard is now in Version 1.6, published in 2015; the corresponding AES standard is due

Table 7. Recommended fields for VorbisComments metadata

Recommended Field	Description
TITLE	Title of the work.
VERSION	May be used to differentiate multiple versions of the same TITLE.
ALBUM	The collection name to which this track belongs.
TRACKNUMBER	The track number of this piece if part of a specific larger collection or album.
ARTIST	The author(s), creator(s) or composer(s) of the work.
PERFORMER	The artist(s) who performed the work. Omitted if it is the same as ARTIST.
COPYRIGHT	Copyright attribution.
LICENSE	License information.
ORGANIZATION	Name of the organization or label producing the track.
DESCRIPTION	A short text description of the contents.
GENRE	A short text indication of music genre.
DATE	Date the track was recorded.
LOCATION	Location where track was recorded.
CONTACT	Contact information for the creators or distributors of the track.
ISRC	The International Standard Recording Code.
METADATA_BLOCK_PICTURE	Embedded digital image.

to be revised in 2016. In 2015, EBU generalized the technical metadata area of EBU Core with the Audio Definition Model (ADM) (EBU Tech 3364), which enables descriptions of audio containing tracks of mixed formats.

AES also published complementary standards for embedding technical metadata in MPEG Layer II compressed audio file format (AES41) and for the archiving of analog audio in digital form (AES57, formerly AES-X098B). Administrative metadata for audio production workflow (AES-X155) and the history of signal processing (AES-X098C) are currently in development.

EBU has registered EBUCore with the SMPTE Registration Authority, and continues its development of metadata specifications towards linked

data and semantic web applications. EBUCore has been simultaneously published as a RDF/OWL ontology, which has formed the basis for the development of the W3C Ontology for Media Resources, an interlingua ontology and an associated API.

PBCore

PBCore, first introduced in 2005 with the support of the Corporation for Public Broadcasting, is a community-developed metadata standard for describing analog and digital audio assets primarily in broadcasting. An extension of Dublin Core, PBCore provides elements that enhance description in the areas of instantiation (analog and digital), intellectual content, and intellectual property. PBCore 2.0, introduced in 2011 (updated to version 2.1 in 2015), enhances the ability to draw relationships and include rights information at the instantiation level, including the handling of segments, multi-part assets, and derivatives. The PBCore schema allows external URI references for all element values.

MPEG-7 Audio

The Multimedia Content Description Interface (MPEG-7), developed by the Motion Picture Expert Group, is a suite of ISO standards (ISO/IEC 15938) in 13 parts published between 2002 and 2008. Following a comprehensive approach to describing multimedia content, MPEG-7 allows fast and efficient searching and retrieval. The standard defines the XML-based Description Definition Language (DDL), which serves as the basis for developing Description Schemes (DSs) and Descriptors (Ds). MPEG-7 Part 4 includes structures for describing technical parameters of audio signals such as silence, timbre, harmonic features, spectral features, and signal features, as well as descriptive metadata such as audio signature, musical instrument sounds, melody description, general sound recognition and indexing, and spoken content. The division between technical

and descriptive is blurred since MPEG-7 audio metadata are in part based on the characteristics of the audio itself rather than of human description. These metadata enable searching and filtering based on sound segments, sound characteristics, and lexical inputs. Since its inception, MPEG-7 has spurred research and development in semantic indexing as well as in automatic and interactive extraction and retrieval of multimedia information.

IEEE 1599

The Institute of Electrical and Electronics Engineers published a standard in 2008 for music encoding (IEEE 1599) that provides an XML language to encapsulate a holistic sound object. The goal of this standard is to integrate symbolic computer notations, printed scores, machine rendering, recorded performances, and related objects to enhance real-time human interaction with these facets of a single musical work, as well as between musical works.

FUTURE RESEARCH DIRECTIONS

Digital audio will continue to evolve in a distributed environment with increasing demand for search and retrieval in a multimedia context. The development of the semantic web will bridge audio essence and semantics through automatic and semi-automatic semantic extraction processes. These uses of digital audio necessitate mapping KLV-style metadata to XML, refining syntactic structures to better describe audio essence, developing multimedia ontologies, and harmonizing relationships among metadata elements and schemes.

Audio information segmentation, classification, and retrieval will remain major topics of research, as will automatic speech recognition and audio-enriched metadata extraction based on knowledge of music theory. These audio metadata will form the basis of semantic audio, which will significantly impact not only the production,

transmission, and consumption of audio, but also open up new areas of applications in scientific, social, informatics, business, and artificial intelligence research.

CONCLUSION

By the turn of the 21st century, metadata standards have evolved together with production and transmission technologies from equipment-dependent formats to the Open System Interconnection model (ISO/IEC 7498-1) where digital audio objects are stored and transmitted in a distributed network. Metadata standards have also developed alongside the transition from carrier- and device-dependent audio formats to web-based, personalized delivery. In this new environment, audio metadata enable the re-contextualization, repackaging, and commodification of audio, integrating it with multimedia contextual elements and transforming it into a new cultural product.

KEY TERMS AND DEFINITIONS

Descriptive Metadata: Describe a resource for the purpose of identification, discovery, and retrieval.

Digital Audio: Digital coding of analog audio signals.

Embedded Metadata: Metadata that are stored in the same file that carries the object described by the metadata.

Extensible Markup Language: A markup language that defines a set of rules for encoding textual data recommended for semantic web publishing.

Metadata Schemas: Structures that establish and define data elements, the relationships between them, and the rules governing their use.

Metadata Standards: Specifications or definitions that establish common meaning, usage, and interpretation of metadata.

Semantic Audio: The extraction of symbols and meaning related to audio, including speech and non-speech content.

Technical Metadata: Describe the state, the creation process, and the digital characteristics of a resource.

Multimedia-Enabled Dot Codes as Communication Technologies

Shigeru Ikuta

Otsuma Women's University, Japan

INTRODUCTION

Augmentative and alternative communication (AAC) technologies are widely used, providing students with severe speech, language, and communication difficulties the opportunity to improve their communication, and by extension, their relationships with others. AAC systems utilize assistive technology (AT) devices that range from no-tech to high-tech. Modifying young children's environments by using AT, defined as any tool, device, or adaptation that allows them more ways to gain access to the people, places, and setting where they can be exposed to typical developmental activities, increases opportunities for learning (Sadao & Robinson, 2010). Dell, Newton, and Petroff (2016) described the practical use of such devices in a classroom. Carpenter, Johnston, and Beard (2014) published a text for both in-service and pre-service educators to introduce AT. Jonge, Scherer, and Rodger (2007) provided an opportunity to try to understand the experiences of AT users in the workplace.

A widely used AAC tool, voice output communication aids (VOCAs) utilize single-level or multi-level outputs to convey sounds. Although there are a variety of VOCAs catering to students with different abilities and needs (Inclusive design research center, 2016; RESEARCH AUTISM, 2016), most devices are severely hampered by their low-output numbers and short lengths of time that they can record.

Approximately ten years ago, to address the above problems the present author started using Scan Talk dot codes developed by Olympus Co. (1999). Such codes transform voices and sounds

into two-dimensional dot codes directly outputted on ordinary paper. Students with severe hand, finger, or mental challenges, however, could not correctly trace Scan Talk codes using the Scan Talk Reader. The present author, therefore, used new dot codes developed independently by Gridmark, Inc. (2009) and Apollo Japan (2005) and conducted school activities with original handmade teaching materials overlaid with these dot codes. In our work, just touching the "invisible" dot codes printed on the paper or symbol icons by using a sound pen clearly reproduces voices and sounds. By using the identical sound pen or a scanner pen connected to a tablet or PC, multimedia sources such as movies, Web pages, and PowerPoint files, in addition to voices and sounds, can be reproduced on its screen.

In this article, state-of-the-art dot code technology is outlined, and basic information regarding the creation of original handmade materials using dot codes and the use at both general and special needs schools is presented.

BACKGROUND

Outline of Dot Code Technology

GridOutput Dot Codes

GridOutput (Gridmark, 2009) is a set of novel two-dimensional codes comprising extremely small dots. Such dot codes can invisibly overlay any graphically printed letters, photos, and illustrations with no impact on the designed visual images, meaning that letters, photos, and illustra-

tions can be changed into information-trigger icons. A maximum of four voices and sounds can be linked to each icon, as well as other media such as movies, Web pages, and PowerPoint files. Simply touching the dot codes printed on ordinary paper with a sound pen (e.g., G-Talk or G-Speak) or a scanner pen (e.g., G-Pen) enables students to directly access the corresponding digital information.

To print document content that includes the “invisible” GridOnput dot codes, industry-standard Cyan-Magenta-Yellow-Black (CMYK) processes are required. More specifically, carbon ink that absorbs infrared rays is used only for dot code printing, while non-carbon ink is used to print graphics. The sound and scanner pens read the invisible dot codes using built-in infrared cameras.

ScreenCode Dot Codes

Developed by Apollo Japan (2005), ScreenCode is a microscopic barcode that allows developers to map data onto printed surfaces, such as printed documents. Unlike other data-coding systems that map data onto expensive metallic-based inks, ScreenCode allows users to map data using regular ink similar to that found in household printers. Apollo Japan has recently published their ScreenCode smartphone and tablet application in which the built-in camera of the smartphone and tablet, using a specially designed lens, can identify ScreenCode and reproduce linked multimedia such as movies, audio files, photos, and Web pages on their screen.

Other Dot Codes

Developed by DENSO WAVE, Inc., the well-known QR code (1994) is an open code that anyone is allowed to use; it has become quite widespread as Micro QR codes, iQR codes, SQRCs, and Frame QRs. These QR codes incorporate high-level features such as illustrations, letters, and logos, and provide high-capacity data encoding, small printout sizes, Japanese Kanji

and Hirakana character support, dirt and damage resistance, 360-degree readability, and structured appending features. DENSO WAVE distributes their QR-code-generation programs, QRdraw Ad (DENSO WAVE, 2016a) and QRmaker Ad (DENSO WAVE, 2016b), free of charge.

Developed by TOPPAN TDK LABEL Co., LTD, the Z code (TOPPAN TDK LABEL, 2016) is composed of tiny dot codes and does not spoil illustrations or texts. The Z code is now used to integrate digital media with analog media and assess whether printed matter is genuine or false.

Developed by ZAK Co., the Simple Microdot Code (SMC) (ZAK, 2009) creates a sophisticated algorithm to print data on a 2.5 mm² area that can be decoded with an optical device. These tiny swatches of encoded dots can also be used to trigger electronic links, applications, databases, etc. The SMC dot code patterns can easily be integrated into a print file by end users using any of today’s desktop publishing software that support CMYK printing processes, thus allowing SMC dot code patterns to be placed anywhere on a printed surface, either as a standalone pattern or embedded in a directional graphic element.

Franklin Electronic Publishers, Inc. developed AnyBook (Franklin Electronic Publishers, 2016) using dot code technology, which is a set of reading enhancement products that allow children to hear their parents or a loved one reading any book for a more intimate learning experience, even when these readers are not physically present. These products consist of a reading pen that enables the words and pictures to talk with any book using vocal recording software. A variety of AnyBooks are available; for example, holding up to 200 h of audio, AnyBook Anywhere (DRP-5100) has 420 reusable stickers with pre-recorded sounds that are created using a special glue that does not harm the pages of the books, a headphone jack for private listening, and backup and sharing capabilities with AnyBook Case.

Afaya Technology Co., Taiwan, has developed a dot code incorporating charge coupled device scanning technology, which identifies the printed

K-layer that hides index data in two-dimensional bar codes of four to five ink-coated sheets of paper or books. This technology also includes an MP3 database and a visual-authoring tool. They sell a variety of Afaya-Pens (2016) in cooperation with their business partners and have produced many publications with pre-printed dot codes.

In Japan, under the new Course of Study (revised in 2008), “Foreign Language Activities” in the 5th and 6th grades are required at all elementary schools. The overall objectives of these new activities are “to deepen the understanding of languages and cultures through the experience of foreign language learning; to encourage efforts towards communication; to familiarize children with foreign language sounds and fundamental expressions; and to develop a foundation of basic communication abilities.” (TOKYO SHOSEKI, 2016a) With this as an opportunity, many English textbooks, side-readers, and picture books overlaid with dot codes have entered the market (EC kids, 2016; ECC, 2016; Kumon, 2016; Pendoku, 2016; Sailor, 2016, TAKAHA, 2016; TOKYO SHOSEKI, 2016b). The hope here is that these new foreign language activities may help students acquire conversational English skills more smoothly.

MAIN FOCUS OF THE ARTICLE

Each and every student has individual hopes, needs, and desires, as well as a history of learning. Therefore, schoolteachers ideally should develop original independent content suitable for each individual. Given the challenges in doing so, easy-to-handle and less-costly software and hardware solutions are crucial to schoolteachers for creating original content for students in their class (Ikuta et al., 2013, 2015, 2016).

We have been collaborating with two Japanese venture business companies, Gridmark, Inc. and Apollo Japan, to help students, especially those with various handicaps, by developing original handmade content and conducting fruitful school activities. Gridmark, Inc. has kindly provided us,

free of charge, with their valuable software for creating handmade content for sound pens, allowing us to distribute it to collaborating schoolteachers.

We recently created an original sheet (called a magical sheet) overlaid with GridOnput dot codes. Each sheet, as shown in Figure 1, has 117 “Post-it” sticker icons, which can be taken off and pasted elsewhere. Up to four audio clips can be linked to each icon by using the specially designed software (*NANA.exe*), which was kindly given to us by Gridmark. Schoolteachers can now create original handmade content and conduct school activities in their class without buying anything, instead of using a specially designed linkage table file, *filelist.csv*, that can be opened and edited with Microsoft Excel. In this file, each mp3 audio file is linked to the corresponding dot code icon’s number. The content folder, produced by double-clicking *NANA.exe*, can then be copied onto the Micro SD card of a sound pen. Touching the symbol icons pasted just beside the illustrations and texts with a sound (G-Talk or G-Speak) or scanner pen (G-Pen) plays back the original voices and sounds, as well as multimedia such as movies on the screen of a tablet or PC.

The executable file that can reproduce multimedia has also been distributed to collaborating schoolteachers free of charge; as such, they can edit a specially designed *URLLIST.csv* and replace old movies with new ones. Here, *NANA.exe*, *filelist.csv*, and *the folder* including an executable to reproduce multimedia are sent on request free of charge.

Gridmark, Inc. has just published their software (i.e., *SoundLinker* and *FileLinker*) and make it available to the market; their software can easily link audios and multimedia to dot code symbol icons. The executable file, created with *FileLinker*, enables the *sound* pen, G-Speak, connected to your tablet or PC to reproduce the multimedia sources like movies in addition to the *scanner* pen. More costly software called the *Gridmark Authoring Tool (GAT)*, which can directly overlay the GridOnput dot codes on illustrations or text of a PDF file, is also available now; unfortunately,

Figure 1. Magical sheet with GridOnput dot code symbol icons, G-Speak, and G-Pen

this *GAT software* requires a costly color printer to print the overlaid file.

Apollo Japan has recently published a new application called *ScreenCode*, which can be used with an iPhone or iPad with a built-in camera; note that the built-in camera must have a specially designed small lens to reproduce multimedia such as movies, audio files, and photos already saved on the iPhone or iPad. Entering a uniform resource locator (URL) with a software keyboard also reproduces Web pages. As shown in Figure

2, the present author has started to distribute sheets with *ScreenCode* dot codes free of charge, as schoolteachers do not need to buy the costly software, *Garyu Tensei for Smartphone*. Clearly, *ScreenCode* is a very attractive application for connecting to digital media from a smartphone to the dot codes on paper. University students are now developing original handmade content for younger students at both general and special needs schools, as detailed further in the next section.

Figure 2. Handmade sheet generated by *ScreenCode* and a specially designed lens

SOLUTIONS AND RECOMMENDATIONS

Original Handmade Content and School Activities

The teachers at Honmachidahigashi elementary school in Machida, Tokyo, conducted an activity using dot code symbol icons, as shown in Figure 3, for a 5th grade male student with a reading disability. At the school, the homeroom teacher gave the student a test with a worksheet after finishing each unit, but the student consistently could not answer anything. The homeroom teacher could not understand this.

We provided a sound pen to the homeroom teacher, and she recorded every question using her voice on the sound pen, linking it to the corresponding symbol icons beside each question. The student could now listen to the audio with a sound pen instead of reading by himself.

As the first achievement since the given activity started, the student earned a grade of 70; all of the teachers at the school were at first surprised, but soon realized he had a reading disability. They confirmed the importance of knowing and understanding the difficulties each student faces and trying to remove such difficulties with the help of teaching aids and tools. The homeroom teacher now continues to create suitable content for this student.

A student of Otsuma Women's University, Miki Endo, also created content; as shown in Figure 4-a, younger students can learn about our solar system (NASA 2016) using audio clips and movies. The GridOnput dot codes were overlaid on each planet using the *GridLayouter* software (which has unfortunately been withdrawn from the market); Gridmark, Inc. has just published new software with similar functionality (i.e., the *GAT*).

Younger students at several elementary schools near the university enjoyed the content very much; by touching each planet with sound and scanner pens, they were able to listen to explanations for each planet and watch movies of the correspond-

Figure 3. Worksheet with GridOnput dot code symbol icons

ing planets. A snapshot of such activities is shown in Figure 4-b.

Teachers at the Osaka Prefectural Special Needs School for the Visually Impaired also created handmade content for blind students, in which even student with total blindness could find the symbol icons and listen to the voices with a sound pen by touching the symbol icons beside the three-dimensional stickers with numeric numbers. A snapshot of these activities is shown in Figure 5. Here, the teacher intentionally placed dot code symbol icons all over the sheet such that the students could enjoy finding them and listening to a fortune slip with voices. The teacher also

Figure 4. (a) Handmade sheet with GridOnput dot codes to learn about our solar system and (b) activities at elementary school

created a booklet that could be used at a school event focused on music appreciation.

The present system using a sound pen and handmade content was also introduced to special training school students for the visually impaired. A student with weak eyesight said, with deep emotion, “I am always afraid how I can read picture books for my children in the future. When I try to read a picture book for my child, I have to hold the book to my eyes and cannot look at my child’s face at all; however, now, with the help of this

sound pen, I record my voice beforehand using the recording functionality of the sound pen and can really read a picture book to my child.” The sound pen has been able to realize a dream for people with weak eyesight and the totally blind.

The *ScreenCode* application for iPhone and iPad, recently developed by Apollo Japan, is now put on the market, with multimedia such as movies, photos, audio clips, and Web pages being able to be linked to ScreenCode dot codes overlaid on ordinary paper. A specially designed lens is

Figure 5. Activities with handmade sheet for a totally blind student at the Osaka Prefectural Special Needs School for the Visually Impaired

attached to a built-in camera of the iPhone and iPad; this camera focuses on the dot codes. The augmented reality application *Aurasma* can also reproduce multimedia such as movies by focusing on the trigger illustration with the built-in camera of an iPhone or iPad. Focusing on the trigger illustration, however, is not so easy; a smaller illustration on paper cannot be focused. On the other hand, the *ScreenCode* application, with a built-in camera, can focus fairly well on smaller sized dot code symbols.

Apollo Japan is now distributing “a sample notebook with Screen Code” overlaid with ScreenCode on every page of a blank booklet in which you can write your own messages and link multimedia to the pages quite easily. The present author with university students is now creating handmade worksheets (overlaid with ScreenCode) for younger students at general schools and preparing school activities, as depicted in Figure 6. The present author also created a specially designed sheet with ScreenCode dot codes, as shown in Figure 2, created using the *Garyu tensei for Smartphone* software, and then started to share them with schoolteachers free of charge. Each symbol icon in the sheet can be cut-and-pasted

on any item and linked with multimedia such as movies, audio clips, photos, and Web pages. Figure 7 shows snapshots of using the ScreenCode dot codes with an iPhone; note that the built-in camera is attached with a specially designed lens. Apollo Japan is now developing the system to focus the ScreenCode without using the specially designed small lens; this *ScreenCode* application may promote more widespread use of smartphones and tablets in the classroom.

FUTURE RESEARCH DIRECTIONS

The present author creates original handmade content and conducted many activities at both general and special needs schools in collaboration with schoolteachers not only in Japan but also in the United States, the United Arab Emirates, China, and Oman. All the schoolteachers wish to use easy-to-handle and less-costly software to create their original contents for each student in their class; it is difficult for schoolteachers to obtain the funds to buy costly software and hardware to do so. The software presented in this article, for example, *Garyu Tensei for Smartphone* developed

Figure 6. Handmade content with ScreenCode dot codes

Figure 7. (a) Special lens attached to an iPhone and (b) snapshot of iPhone screen (school activity movie), focusing on ScreenCode dot codes

by Apollo Japan, costs more than 1,000 USD; thus, schoolteachers cannot buy it. Even cheaper software, such as *SoundLinker* and *FileLinker* developed by Gridmark, Inc. for linking audio clips and multimedia files to GridOnput dot codes, are still costly. Collaboration with university professors is crucial to start and continue developing easy-to-handle and less-costly software and creating outstanding original handmade contents for each student in a different set of needs and desires, degree of disability, and learning history.

The present author has conducted many long-term activities with schoolteachers at both special needs and general schools, and performed several assessments of such school activities using the original handmade teaching materials with the present multimedia-enabled dot codes (Ikuta et al., 2013, 2015, 2016). Each student has responded to these activities with confidence and joy, providing that such long-term activities could also improve the students' learning. The various effects noticed during the running of the school activities should be carefully analyzed and classified more in details for each kind of disability, so as to be able to focus the activities more precisely; such analysis is crucial to clarify the usefulness of assistive technology in the classroom.

Through many school activities performed at general and special needs schools, it was noticed that the sound pens require some changes. The positions of the power and audio volume buttons on the new sound pen G-Speak are located just at the pen center, and students with disabilities and in lower grades often make errors. The present author therefore suggest that Gridmark moves these buttons to the side of the pen. The sound pens with Wi-Fi and Bluetooth connectivity could be used in the near future classroom. More effective uses of such new sound pens with original contents should be explored by the researchers in collaboration with schoolteachers in many parts of the world.

The help of university students is also crucial to developing original handmade content, since schoolteachers, especially in Japan, always have too much to do in their daily jobs. Collaboration with schoolteachers is very important and attractive for university students, especially those who wish to become teachers; these university students can learn much from current schoolteachers.

Good relationships and collaborations with developers, Gridmark, Inc., and Apollo Japan are also crucial to continuing and developing the present project. Also, funds provided by the

Ministry of Education, Culture, Sports, Science and Technology, Japan, and the Institute of Human Culture Studies, Otsuma Women's University are essential for us to purchase software and hardware, and provide them to schoolteachers free of charge.

CONCLUSION

In collaboration with schoolteachers, a variety of original handmade content has been created and various activities at both general and special needs schools have been conducted. The present author has created specially designed sheets with "Post-it" symbol icons overlaid with dot codes; such sheets have been provided with sound pens and software to collaborating schoolteachers free of charge, so that they can create handmade content for students in their classrooms themselves without purchasing anything.

We asked schoolteachers to create original handmade content for students in their own classes instead of purchasing teaching materials already on the market, since each student has his or her own needs and desires and own history of learning. Perfect teaching materials and tools for one student do not always perform well with other students. Easy-to-handle and cheaper software and hardware are required if the schoolteachers are to proceed with these voluntary activities. Collaboration with software and hardware companies and their kind help, therefore, are an important issue for the development of focused teaching materials and school activities.

Support given by the Grants-in-Aid for Scientific Research and the Institute of Human Culture Studies, Otsuma Women's University, is also important for ensuring the continuation of larger collaborations with worldwide schoolteachers. The help of university students is also a strong motivation for schoolteachers who wish to develop individual content for each of their students. Collaborations with foreign schoolteachers in the United States, United Arab Emirates, and Oman

are also very important to extending and assessing present school activities performed in the classroom with new information communication technologies.

ACKNOWLEDGMENT

The author thanks "Grant-in-Aids for Scientific Research" (C) (#22530992 and 16K04844) and the "Institute of Human Studies" (s2605, s2713, and s2810) at Otsuma Women's University. The author also thanks Fumie Shimada, Chikako Kaneko, Miki Endo, Erika Kaneko, and Noriko Kuroda for their collaborations. The author would like to heartily thank Enago (www.enago.jp) for their English language review.

KEY TERMS AND DEFINITIONS

Assistive Technology: Assistive technology (AT) devices range from no-tech to high-tech and help to properly assess the correct communication systems for students with severe speech-language deficits; as such, professionals work with students, teachers, and individuals who interact with students on a daily basis.

Communication Aid: Communication aids based on augmentative and alternative communication (AAC) technologies have been widely used to provide students with severe speech, language, and communication difficulties the opportunity to achieve successful communication and relationships with others.

Dot Code: Invisible dot codes developed by Gridmark, Inc. are a novel two-dimensional code

technology consisting of extremely small dots practically imperceptible to the human eye. Each symbol icon can be linked to up to four audio clips. Multimedia such as movies can also be linked to the same symbol icon. A simple touch by sound and scanner pens on the symbol icon enables links between paper and digital content.

Handmade Content: *Original handmade* teaching content plays a key role in learning, as each student has different thoughts, feelings, needs, and desires. Independent teaching material should be prepared and used for each individual, especially in preschool and special needs classrooms.

Magical Sheet: This specially designed sheet has the order for each dot code imprinted on each symbol icon. The sheet has additional symbol icons with audio-recording functionality and mode changing. The icons can then be taken off and pasted onto a target object and touched with sound and scanner pens. The “magical sheet” enables the costly GridOnput system to be used at any school at a low cost.

Scanner Pen: Scanner pens such as the G-Pen can read dot codes printed on paper and play back multimedia (such as movies) on the screen of a G-Pen connected to a tablet or personal computer.

School Activity: School activities at special needs schools can be improved through the use of *original* and *individual* handmade teaching materials and aids suitable for each student with disabilities.

Sound Pen: Sound pens, such as G-Talk and G-Speak, reproduce original voices and sounds by simply touching the dot-coded symbol icons or the dot codes directly overlaid on the paper.

Voice Output Communication Aid: Voice Output Communication Aids (VOCAs) are widely used AT devices that utilize single-level or multi-level outputs to convey sounds. While a variety of VOCAs exist that cater to students of different abilities and needs, most devices are severely hampered by their low-output numbers and short recording times.

Semantically Enhanced Authoring of Shared Media

Charalampos A. Dimoulas

Aristotle University of Thessaloniki, Greece

Andreas A. Veglis

Aristotle University of Thessaloniki, Greece

George Kalliris

Aristotle University of Thessaloniki, Greece

INTRODUCTION

The rapid evolution of digital technology, among others, has revolutionized multimodal content production and distribution processes, propelling novel mediated communication services. Interactive media authoring and sharing technologies are currently being launched, bringing forward new ways of audiovisual (AV) content exchange. Web documentaries (web-docs) and hypermedia have appeared as a natural extension of filmed documentaries and digital TV, inheriting also some of their advantages. Narrative documentaries adopt AV mediated communication mechanisms that humans have been accustomed to be informed and communicate with each other, so that they are more informative and vivid compared with other documents (books, web-pages, multimedia, etc.). Thus, AV-documentaries, web-docs and generally interactive videos and hypermedia can be more easily distributed and attended from most ages and social groups (Dimoulas, Veglis, & Kalliris, 2015; Dimoulas, Kalliris, Chatzara, Tsipas, & Papanikolaou, 2014a; Kotsakis, Kalliris & Dimoulas, 2012; Matsiola, Dimoulas, Kalliris, & Veglis, 2015; Veglis, Dimoulas & Kalliris, 2016). Moreover, the continuous evolution of the computing power and the digital storage media favor digital video production and distribution. This is also fueled by the increased network speed, the efficiency of compression algorithms and the continuous

decrease of the corresponding costs (Kotsakis et al., 2012; Dimoulas, Kalliris & Veglis, 2014b). High quality AV capturing equipment is currently available at low cost and size as part of smart phones and other mobile computing terminals with inherent networking capabilities, allowing easy AV-content production, contribution and sharing (Atzori, Delgado & Giusto, 2012; Dimoulas & Symeonidis, 2015; Dimoulas et al., 2014a; 2014b; 2015; Sidiropoulos, Konstantinidis, Kotsakis & Veglis, 2015; Veglis et al. 2016; Vrysis, Tsipas, Dimoulas & Papanikolaou, 2015). In this context, more and more users are involved in the AV production and consumption chain, so that creative experience and AV media culture are cultivated. Nevertheless, AV media related achievements are still far from the progress that has been made in textual information management during the outspread of social media and Web 2.0 services.

Interactive services have also been introduced into the AV production industry, aiming at augmenting human-machine interaction (HMI). AV content is enhanced in functional and informative level, further stimulating users to actively participate in arousing interactive scenarios. While the transition from Web 2.0 to Web 3.0 is ongoing, intelligent AV-content processing and management services are pursued, facilitating users' involvement on media sharing, commenting and multichannel publishing. In this context, semantic annotation, social tagging and meta-

DOI: 10.4018/978-1-5225-2255-3.ch562

processing can be part of collaborative media syncing, editing and multimedia management, thus propelling more sophisticated authoring (and sharing) of semantically-enhanced media. Although these technologies are rapidly evolving, there are still open challenges regarding upcoming semantic web services (De Bra, Freyne, & Berkovsky, 2013; Dimoulas et al., 2014a; 2014b; 2015; Dimoulas & Symeonidis, 2015; Matsiola et al., 2015; Monaghan, Handschuh, & O'Sullivan, 2011; Veglis et al. 2016). This chapter examines current trends and future perspectives of semantically-enhanced media /multimedia (SeMM), considering all forms of non-linear storytelling, sharing and authoring (web-docs, multichannel media publishing, interactive videos, adaptive hypermedia and generally multimedia services). Background is presented providing basic definitions, involved technology, achieved progress and limitations. Recommendations and future research direction are then stated, aiming at serving a two-folded target: firstly, to present new, user-friendly forms of collaborative creativity, multimedia authoring and storytelling that current technology allows to be successfully deployed; secondly, to suggest innovative adaptation mechanisms that can be utilized in both the media production and consumption ends, allowing for intelligent media management and augmented semantic interaction services to be launched. In this context, the importance of SeMM toward the transition to the Web 3.0 era is revealed.

BACKGROUND

Nowadays, hybrid models of mixed Page-Based Media (PBM) and Time-Based Media (TBM) are the most common multimedia web content, combining both spatial and spatiotemporal arrangement of all media entities (i.e. text, images, audio, video). These so-called Multimodal Media Assets (MMA) (Veglis et al., 2016; Dimoulas et al., 2015) may include multichannel audio and video,

non-linear animations and photos, titles and more elongated textual descriptions that offer versatile presentation of information, enabling different views and audio-tracks selection, multilingual narration and subtitling. MMA schemes have many similarities to the early digital versatile disc (DVD-video) and are closer to the content entities and structures that contemporary web-docs and hypermedia utilize. The term hypermedia refers to hyperlinked multimedia, the same way that hypertext is about grouping relevant information in the form of hyperlinked PBM nodes. It is known that, while the term appeared in the early '90s, it was put aside since then, an issue that is associated to the broader meaning that the multimedia definition received. Thus hypermedia can be considered as a subcase of multimedia web services. Today, both terms are used somewhat as synonyms, with the multimedia definition to be wider, incorporating both TBM and MMA compositions with linear and non-linear navigation, but also referring to new, more sophisticated forms of creativity, digital storytelling and interaction. For this reason, the terms media and multimedia are mostly used in this chapter, instead of hypermedia. Obviously, there are still many technical issues and limitations associated with the involved diversities (i.e. different content types, formats and publishing channels, encoding and reproduction compatibilities, HMI and authoring technologies, semantics and meta-data management, etc.), so that SeMM is more than simple combinations of shared MMA entities.

One of the key terms of hypermedia is interactivity, which has advanced with the evolution of hypertext technology. Along with interactivity, new forms of digital storytelling are considered and pursued, aiming at providing rich media experience through highly valued Quality of Experience (QoE) media services having appropriate emotional impact on the users' side, thus stimulating their active engagement (Kalliris, Matsiola, Dimoulas & Veglis, 2014; Kotsakis, Dimoulas, Kalliris & Veglis, 2014; Matsiola et al.,

2015). Hence, content contribution and sharing models along with social tagging and semantic interaction services can be considered as contemporary interaction forms that can be very useful in various ways. Today, every Internet user acts both as a receiver and transmitter of information by generating and disseminating textual content, along with audio, video and generally multimedia components (Dimoulas et al., 2014b; 2015; Veglis & et al., 2016). This is also the case for the user generated content (UGC) in social networks.

As previously implied, not all of the features that have been already achieved and adopted in textual information and PBM media can be easily applied and accommodated to the cases of TBM and MMA. Indeed, there are still many open issues regarding efficient AV content description and management automation, but also interoperability with transparent multimedia access. Hence, content-based searching and retrieval techniques are currently being implemented, using multimodal content detection, segmentation and summarization-highlighting algorithms along with intelligent processing and hybrid expert systems for pattern recognition and semantic analysis purposes (Cordara, Bober & Reznik, 2013; Dimoulas, Avdelidis, Kalliris & Papanikolaou, 2008; Dimoulas, Papanikolaou & Petridis, 2011; Diou et al., 2010; Kotsakis et al., 2012; Vegiris, Dimoulas & Papanikolaou, 2009). Furthermore, while much progress has been made in textual data mining approaches, semantic interaction and conceptualization efforts are still left behind, not only in AV-related media, but also for text and general PBM information, as well (Dimoulas et al., 2014b; Diou et al., 2010; Symeonidis & Mitkas, 2005; Veglis et al., 2016). This hysteresis in the progress of AV versus textual information processing also explains why hypermedia did not flourish as hypertext. As it is analyzed later on, intelligent MMA processing is also considered to be a crucial prerequisite for the deployment of largescale semantically-enhanced collaborative multimedia authoring and sharing.

SEMANTICALLY ENHANCED MULTIMEDIA

Multimedia Semantics and Authoring Tools: Issues, Controversies, Problems

The term Multimedia (instead of media) in the SeMM model emphasizes the fact that multiple content types and communication means are usually encountered and involved in the associated sharing and authoring processes (without the necessity for each one of them to encompass all kinds of media entities). Many Web-TV platforms and popular AV social media (i.e. Youtube, Vimeo, Ustream, SoundCloud, etc.) have propelled AV-content contribution and dissemination (Dimoulas et al., 2014b; 2015; Tsipas, Zapartas, Vrysis & Dimoulas, 2015). These web environments are currently massively utilized from a variety of simple users, experts and media professionals for both AV content consumption and production, offering on demand upload-access and live streaming services, along with online processing, annotation, commenting, authoring and sharing throughout the entire Internet community (Dimoulas et al., 2014b; 2015; Spyridou, Matsiola, Veglis, Kalliris, & Dimoulas, 2013; Veglis et al., 2016). The availability of multiple broadcasting media led to the implementation of multichannel publishing models, offering alternative navigation routes and new forms of interactivity. In this context, collaborative media authoring and sharing can be considered as a multichannel publishing sub-case, where semantic meta-data and content quality metrics can be exploited toward intelligent cross-media publishing and mediated communication models (Kalliris et al., 2014; Kotsakis et al., 2014; Veglis et al., 2016). In most cases, these processes need to be expedited with the use of intelligent systems and media agents, so that content production, processing and authoring guidelines can be provided as they needed (especially from the average user) along with content recognition and semantic

Figure 1. The processes of semantically-enhanced multimedia production, authoring and sharing

labeling automations (Dimoulas & Symeonidis, 2015; Sidiropoulos et al., 2015; Tsipas et al., 2015; Vrysis et al., 2015). As it is depicted in Figure 1, a recent modeling approach is the utilization of the so-called multimodal media agents (M3A) and multi-agents (M4A), which refer to media services able to sense its surrounding environments (at multiple levels, semiotic modes and/or communication channels) and autonomously adapt on their changes, responding on behalf of other (software) entities and human interactions (Matsiola et al., 2015). Hence, user-related adaptations and social networking intelligence are incorporated into mediating mechanisms that can facilitate multimedia communication, authoring and sharing, thus offering augmented and semantically-enhanced interactions, both at the media production and consumption ends.

In any case, multimedia production involves two complementary phases: content production (including UGC contribution) and authoring. The former can be delivered with a variety of tools and services, namely: discussion groups, weblog, collaborative publishing, Peer-to-Peer, XML

Syndication (Dimoulas et al., 2014; Monaghan et al., 2011). The latter is usually accomplished with the use of software programming, declarative languages, web developing and scripting tools (Dimoulas et al., 2014b; 2015; Dimoulas & Symeonidis, 2015; De Bra et al., 2013; Dos Santos & Muchaluat-Saade, 2012; Matsiola et al., 2015). These tools have been utilized during the last years for the development of user friendly web-doc authoring platforms that offer easy operation, increased creativity choices, with different distribution and pricing models. As a consequence, many worth-mentioning featured web-docs have been appeared during the last decade, which fused and projected new levels of creativity, user interaction and participation, outclassing multichannel media publishing. User engagement is enhanced by means of adaptation and personalization, collaborative social tagging, resources recommendation and semantic interaction. The latter are dominant in the so-called adaptive hypermedia systems (AHS), which are very common in mediated learning and public administration services, narrative tools and serious

gaming approaches, AV heritage and cultural projects (De Bra et al., 2013; Dimoulas et al., 2014a; Dos Santos & Muchaluat-Saade, 2012; Kalliris et al., 2014; Kotsakis et al., 2014). In addition, much effort is put for inter-platform compliance and interoperability, although there are still issues that need to be addressed, especially for the majority of upcoming Web 3.0 services (Dimoulas & Symeonidis, 2016; Dimoulas et al., 2013; 2014; 2015; Veglis et al., 2016). Hence, while multimedia semantics require massive /diverse content labeling and meta-data processing through time-consuming and tiresome users-enabling tasks, media authoring and browsing decisions can offer such kind of ground-truth information in an easier, entertaining and self-extracted way. These potentials of semantically enhanced multimedia (through collaborative authoring and sharing models) have not been fully revealed or exploited yet, and are attempted to be enlightened in the current chapter.

Solutions and Recommendations: Modeling Semantically-Enhanced Authoring of Shared Media

SeMM authoring involves the incorporation of different MMA into various dialogic modes and HMI scenarios, including media sharing, UGC posts and comments, which is usually accomplished through the collaboration of many different users and groups. Semantic interaction, content annotation and social tagging that are usually involved in Web 2.0/3.0 services can be augmented by and/or combined with the multimedia authoring choices. Thus, production organization and scripting can be part of the annotation and visualization meta-information (Ma, Liu, Wang, Teng, & Dai, 2012), while editing and authoring information can be logged into semantic meta-data (Dimoulas et al., 2014a; 2015). Most of the AV-authoring tasks (i.e. AV-production, clip selection-editing, navigation flow programming, etc.) can contribute to content description and meta-processing (i.e. keyword labeling, semantic tagging, topic and context classi-

fication, event detection-segmentation, long-term story summarization-highlighting, etc.). In fact, these tasks can now be easier and more creatively completed as part of the authoring process and not as separate obligatory annotation procedures. Similarly, end-users' interactions can also provide collaborative feedback for hypermedia adaptation and personalization, search-log-based annotations, social tagging and media recommendation (Dos Santos & Muchaluat-Saade, 2012; Monaghan et al., 2011; Tsikrika, Diou, de Vries & Delopoulos, 2011; Tsirellis & Delopoulos, 2011). Hence, storyline extraction, semantic conceptualization, intelligent content-based searching and retrieval can be supported, offering increased media management automation. Along with these, state of the art pervasive context- and location-aware services, serious games, ubiquitous mobile computing and augmented reality further enhance HMI experience, extending users' participation through a plethora of platforms and interface terminals (Atzori et al., 2012; Cordara et al., 2013; Dimoulas et al., 2014a; 2014b; 2015; Dimoulas & Symeonidis, 2015; Kalliris et al., 2014; Kotsakis et al., 2014; Matsiola et al., 2015).

A semantically enhanced media authoring model (SeMAM) is proposed in Figure 2, where the term authoring has a broader meaning, incorporating all the processes of content (and meta-data) production, processing (selection, editing, etc.), programming (multimedia authoring) and sharing, thus integrating the previously mentioned multimodal semantic interaction, context-awareness and adaptation features. Based on this model, MMA entities are assembled along with semantic and storytelling meta-data, forming the Semantically-enhanced Multimedia Assets (SeMMA), which correspond to the SeMM resources involved in an authoring project. SeMMA incorporate basic multimedia communication and interaction functionalities and can be combined as building blocks of semantically-enhanced multimedia storytelling services (SeMMSS), favoring the construction of semantic composition-decomposition models. Thus, semantic meta-data of all the edited-

authored assets are also assembled, generating a composite semantic outcome. In this context, a complex semantic analysis tasks is delivered via semantic decomposition-composition of all the combined hypermedia assets and their editing (/authoring) decision lists (Dimoulas et al., 2014a; 2015). The construction of SeMM/SeMMSS repositories promotes sophisticated management with improved content selection, adaptation and reuse capabilities in the entire media life-cycle. The above are graphically presented in the upper part of Figure 2, where tools and main processes of the entire media lifecycle are depicted. It is obvious that an infinite number of users and user-groups can participate throughout the end-to-end shared-media chain, where the separate roles of producers and consumers no longer exist.

A diversity of devices is also exploited offering different features (depicted in lower part of Figure 2). Specifically, servers and powerful cloud computing terminals can be used for content storage, processing and intelligent semantic analysis services. Mobile terminals and their multimedia sensors are applicable in pervasive and/or immersive applications, while future iTV sets will allow for easy multimedia browsing that can be offered to the mass population without requiring special skills and knowhow. Furthermore, intelligent systems and media agents (M3A, M4A, etc.) are expected to play a very crucial role, sensing and adapting to the users' needs, while diminishing large-scale content and meta-data heterogeneity. Hence, content recognition and semantic conceptualization, voice commanding and multilingual adaptation or even virtual presentation through avatars and digital characters can be deployed, diminishing interfacing limitations (especially in mobile terminals), while facing various issues related to users' privacy. In addition to the versatile and/or multilingual information structuring, SeMMSS offer new presentation capabilities. Following the citizens-journalism paradigm, multiple UGC contributions on the same story can provide different points of view, offering increased user experience (i.e. multi-view selection, augmented

projection, 3D-reproduction, panoramic and time-lapse virtual navigation, etc.). This can be very constructive in heritage projects, promoting multichannel content enhancement-restoration, archiving and documentation. Again, all these processes and their multimedia consumption counterparts can also contribute to semantic meta-data enhancement. On the other hand, security issues arise regarding systems, content rights and users' privacy, creating further difficulties and computational overheads, but also requiring the standardization of applicable mechanisms (Dimoulas & Symeonidis, 2015; Dimoulas et al., 2014a; 2014b; 2015; Kotsakis, Mislow, Kalliris & Matsiola, 2015; Matsiola et al., 2015; Sidiropoulos et al., 2015; Tsipas et al., 2015; Vrysis et al., 2015). The answer to these questions will determine future research directions and progress of hypermedia.

FUTURE RESEARCH DIRECTIONS

Considering the processes that SeMMSS authoring and sharing involve, there are many functional issues and technical challenges associated with the increased processing and bandwidth demands, and the applicable interaction modes that need to be properly addressed. It is quite difficult to encounter examples of multimedia services that incorporate all the above augmented interaction concepts. Neither it is easy, as in the case of text and images, to post, process online and author AV material in multimedia storytelling. One of the reasons can be found on the very interdisciplinary nature of web-docs and hyper-videos. Multimedia web authoring technologies cannot be easily adopted and utilized by the creators, since they usually don't possess software programming skills and knowhow. Thus, a plethora of user friendly web-doc authoring and hypermedia platforms were developed during the last years. Many of them appear in the cyberspace with many ambitious plans but soon disappear. This fact implies that although a high demand exists due to audience

Figure 2. An integrated semantically enhanced media authoring model (SeMAM)

attraction for such kind of expression media, a viable and sustainable business model has not yet been found for these platforms. Furthermore, large-scale interoperability between different media formats, terminals and platforms is difficult to achieve, while security issues remain crucial, especially for augmented hypermedia services (Dimoulas et al., 2014a; 2014b; 2015; Veglis

et al., 2016). Similarly, censorship actions are required and are expected to be more demanding for AV content (Chen & Wang, 2010; Koumartzis & Veglis; 2011).

Another important issue is related to the fact that multimodal intelligent content processing and semantic interaction techniques have many prerequisites and they have not yet reached a

maturity for large-scale real world applications. Nevertheless, research is ongoing, investigating new descriptive AV-features (Cordara et al., 2013; Dimoulas et al., 2011; Kalliris et al., 2014; Kotsakis et al., 2012; 2014; Vegiris et al., 2009), flexible ground truth acquisition and linking mechanisms (Monaghan et al., 2011; Tsikrika et al., 2011; Tsirelis & Delopoulos, 2013), hybrid smart systems and multimodal decision-making approaches (Dimoulas et al., 2008; 2011; Diou et al., 2010). In this context, emotional control, augmented interaction, content filtering, semantic annotation and retrieval are further promoted (Chen & Wang, 2010; Dimoulas & Symeonidis, 2015; Kalliris et al., 2014; Kotsakis et al., 2012; 2014; Matsiola et al., 2015). Perhaps, this is the real opportunity for the proposed SeMAM model to simultaneously serve, integrate and enhance all the augmented interaction and adaptation features of the future semantic-web services.

CONCLUSION

The current chapter focuses on the technologies of semantically-enhanced authoring of shared media. Current trends and future perspectives are analyzed. A semantically enhanced media authoring model (SeMAM) is proposed, integrating most of the expected progress in augmented user interaction and the upcoming Web 2.0/3.0 services. The targeted Semantically-enhanced Multimedia Storytelling Services (SeMMSS) aim at engaging audience members individually, validating their involvement and positively reinforcing personal participation in the narration. The expected result is intense loyalty, long-term engagement and a desire to share the experience. Although there are many issues that still require careful attention, current state of the art and research progress reveal that semantically-enhanced (collaborative) authoring of shared media will dominate. Hence, new perspectives are offered for the preservation of AV documents from the past, the exploitation

of present and upcoming multimedia technologies and their dissemination with added value storytelling services in the future.

KEY TERMS AND DEFINITIONS

Hypermedia: Combination of the linking mechanisms of hypertext and the multimodal presentation of information that is inherent in multimedia.

Multimodal Media Agents (M3A): Media services able to sense its surrounding environments (at multiple levels, semiotic modes and/or communication channels) and autonomously adapt on their changes, responding on behalf of other (software) entities and human interactions.

Multimodal Media Assets (MMA): A hybrid model of mixed time-based and page-based media (TBM, PBM) that are combined in non-linear presentation forms.

Semantic Interaction: Multimodal feature-based HMI utilizing artificial intelligence for concept recognition, semantic conceptualization and communication.

Semantically-Enhanced Media Authoring Model (SeMAM): A multimedia storytelling and authoring model that combines semantically-enhanced multimedia assets (SeMMA) with additional meta-data related to authoring decisions, augmented interaction and semantic feedback.

Semantically-Enhanced Multimedia (SeMM): Multimedia resources enhanced in semantic level through meta-data provided from many different users and groups, during the processes of production, authoring, sharing and consumption.

Semantically-Enhanced Multimedia Assets (SeMMA): Composite assets containing multimodal media (MMA) with authoring and semantic meta-data (SeMM serving as SeMMSS building blocks).

Semantically-Enhanced Multimedia Storytelling Services (SeMMSS): Multimedia services that combine various semantically-enhanced multimedia assets along with semantic meta-data and associated storytelling properties.

Web-Documentary: Documentary delivered through web, usually exploiting non-linear narration with multiple media and enhanced interaction scenarios.

Transmedia and Transliteracy in Nemetical Analysis

Michael Josefowicz

Nemetics Institute Kolkata, USA

Maria Nieves Lorenzo Galés

The Transformation Society, Spain

INTRODUCTION

The increasing diversification of interconnected media platforms, which provide a complex discourse, demands an effective use of the space that is now called “transmedia.” This article provides terms and definitions for transmedia and for the new set of personal skills and abilities required to participate in it: “transliteracy.” It also presents the nemetic system, which facilitates analyzing, tracking, and visualizing communication interactions in virtual transmedia environments.

Since humans started to use both gestural and oral codes to communicate, messages have been elaborated and expressed differently when different communication channels were in use. In recent times, with the dawn of radio and television, that fragmentation of content has become of interest to researchers (Steinberg, 2012), and has been identified as a characteristic of mass media (McLuhan, 1994).

With social media, content is fragmented across multiple virtual and physical platforms, with varying degrees of interaction that add complexity to social communication. Interactivity among multiple authors and multiple audiences generates dynamic “cross-media” seriality, “transmedia narrative” that has been studied from educational, entertainment, and sociological points of view (Dena, 2009).

Learning to use these media requires skills beyond the traditional listening and reading, to be able to integrate multiple messages in multiple codes, as an essential skill both for personal and professional communication. This transliteracy is a complex ability of intertextual navigation, the strategy for coding and decoding the multidiscourse in the digital ecosystem.

These recursive communication experiences are the subject of recent research (Duarte, 2014) that explores cognitive patterns in narrative that can be represented through geometric models, consolidating the use of the term “fractal narrative” in the transmedia context. The aim of this multilevel analysis is to take into account individual discourse (micro level), collective interaction (meso level) and community knowledge building (macro level). Interested readers will find a practical example of this in the documentation of the co-creative process that led to Daniel Durrant’s representation of a NEME (Figure 2 of this article) (Nemetics Institute, 2015).

In December 2010, Mark Frazier had explored the fractal essence of digital discourse, and debated with Spiro Spiliadis, Daniel Durrant, and Michael Josefowicz the possibilities of expressing its complexity using a symbolic language (Frazier, 2010). After this early work with Ebdish (Emergent by Design’ish), the nemetic system has emerged as a more elaborated code to express and visual-

ize interactive communication processes in the transmedia ecosystem (De, 2014).

BACKGROUND: TERMS AND CONCEPTS

Transmedia

The term “transmedia” is attributed to Marsha Kinder, who in 1991 used it to refer to an emerging entertainment supersystem, involving intertextuality and multiple sources with different levels of interaction (Kinder, 1991). It applied to tools, processes, and concepts, and opened the door to media that had not been invented then, such as wearables, implants, or augmented reality devices.

In 2003 Henry Jenkins described a process of “transmedia storytelling” in which “each medium does what it does best, so that a story might be introduced in a film, expanded through television, novels, and comics, and its world might be explored and experienced through game play.” (Jenkins, 2003) Later, he defined transmedia storytelling as a process “where integral elements of a fiction get dispersed systematically across multiple delivery channels for the purpose of creating a unified and coordinated entertainment experience.” (Jenkins, 2007)

Probably the best-known example of transmedia storytelling is the Star Wars franchise. The fictional universe of Luke Skywalker, Yoda, Han Solo, Darth Vader, and Lord Sith is created through the synergy of films, books, role playing games, comics, video games, toys, and animated shows, to create a collective imaginary world. But transmedia storytelling is not limited to the entertainment world.

The notion of multiplatform narrative is expanding now to encompass every type of human communication, including marketing (Tenderich, 2014), political debates (Costanza-Chock, 2014), or personal learning networks (Richardson & Mancabelli, 2011). There is a need to identify the skills required to use transmedia, the processes

for teaching and learning transmedia skills, and the techniques to analyze transmedia production and its metadata.

Transliteracy

The evolution from media to transmedia requires individuals to pass from personal linear communication skills and abilities (reading, writing, speaking, etc.) to intertextual skills. They include not only analogy, correlation, mental association, context awareness, or synthesis, but also empathy, engagement, and other emotional appreciations, essential to integrate and combine fragments of meaning into the holistic comprehension of a story.

The combination of these complex abilities can be understood as a new competency called transliteracy. Transliteracy has been defined as “the ability to read, write and interact across a range of platforms, tools and media from signing and orality through handwriting, print, TV, radio and film, to digital social networks.” (Thomas, 2005)

In transliteracy, a coherent discourse is perceived through a series of transmedia fragments. It requires participants to move from discrete, perceptive skills to compound, intangible projective skills that can facilitate strategic thinking and collective problem solving. Interactions such as debating, negotiating, conciliating, or collaborating on social platforms are high value-added skills and become the energy for emerging collective creativity.

It would be impossible, for example, to understand the phenomenon of global warming and its varied impacts, without some comprehension of how the climate changes; the effect of human activity on the atmosphere; human migratory patterns; changes in food sources and food production due to changes in land, oceanic, and atmospheric conditions, and thus on refugee crises and terrorist activity, as well. No one medium or information source is capable of adequately presenting all these interrelationships, but if we are able, not only to “read” information from a variety of sources, platforms, and media, but to integrate it,

and understand it as a complex holistic tangle of phenomena, we are using transliteracy to gain a higher level of consciousness, or “mindfulness,” about the subject.

Both transmedia and transliteracy are going to change the way we perceive learning and professional training, in universities and professional environments. Language and communication skills, necessary to understand and produce useful knowledge, are more and more related to the abilities to create, join, and maintain communities of interest, and build personal digital networks (Rajagopal, 2012).

Nemetics

Where transmedia is the framework for communication, and transliteracy is the skill for interaction, Nemetics is the analytic tool. Nemetics functions as a fractal meta-language that facilitates communication among researchers in different disciplines to debate about complexity. The multilayer nemetics system provides a methodology for connectivist action-research and action-reflection in transmedia, including several meta-codes for visualizing procedures and results.

The essentials of Nemetics can be summarized in a simple mnemonic acrostic, which describes learning in any context at any level. At its most effective it is:

- Notice without preconceptions (N).
- Engage without judgment (E).
- Mull before communicating or acting (M).
- Exchange in the appropriate way and time (E)

This basic path, (Notice. Engage. Mull. Exchange,) recalling the traditional Bloom taxonomy (Anderson et al. 2001), retrieves four action levels that may or may not be performed during interactions (after each verb, add the option, “or not”).

The whole conversation is then conceptualized as a single identified process, a NEME that can be seen as a coherent unit, represented visually by the

interactions that took place during the debate. The analysis of these nemes shows patterns and waves of exchange that offer extremely rich information (big data) both about the media environment and the participants. The basic initial model is the communicative sociogramme [Figure 1].

At the individual level, a NEME translates as a meta-cognitive routine; at collective levels, the study of NEME patterns can be useful for showing mental models that can serve as universals in further communicative analysis, and in designing debate strategies.

Taken as a unit, a NEME routine - that concludes with consensual knowledge - can be the starting point from which new debates can arise. This recursivity had already been studied in The Knowledge Forum, another international Computer Mediated Communication experience (Bereiter & Scardamalia, 2006), and has been identified as a path into high order thinking (HOT) processes (Rehage, 1994).

From routine building to big data analysis, nemetics includes the dimension of self-reflection, professional development, and organizational transformation. The obtained global vision contributes to leadership and resource management, focused on integrated learning - self and collective - and helps expand consciousness and engagement towards complex problem solving.

Nemetics helps express a new way of thinking about human communication that involves co-creation in complex adaptive/creative environments, and is being developed by the International Nemetics Institute: Care is taken not to define the discipline or its boundaries very rigidly. This is because once it is rigidly defined it also rigidly limits the development of the subject, its evolution and expanse it might cover. In short, any rigid definition would limit the discipline's adaptability to future changes in human conceptual understanding and knowledge or application in a different domain than what is envisaged right now. (De, 2012)

Figure 1. Communicative sociogramme. The graph represents a network of 40 Twitter users whose recent tweets contained “nemetics,” or who were replied to or mentioned in those tweets, taken from a data set limited to a maximum of 18,000 tweets. The network was obtained from Twitter on Monday, 06 July 2015 at 22:51 UTC.

© 2015 Marc Smith, used with permission.

Used as the meta-language for recursive analysis, nemetics shows interactive thinking processes, collaborative debates and a collective cognitive resonance, through debate, discussion, negotiation, and compromise. This nemetical world is hierarchical, in the sense commonly used in complexity discourse, and it is composed of several nested spheres:

- NEMES,
- nemiString,
- nemiTube,
- nemiPlex,
- nemiCell,
- nemiShape.

Avoiding bottom up or top down hierarchies, the nemetic language works as in concentric spheres, from inside to outside, and from outside to inside. Any sphere can be seen as a NEME, where the proximate inner sphere is the source of energy. The proximate outer sphere is the source of constraints [Figure 2]. In addition, there are flows of energy within and between spheres.

This nemetic code can be used as a common language to shape complexity, and the fuzziness of the code is the source of its strength. It has allowed networks to research and exchange about innovation, education, history, political economy, design, or art across the fields of different disciplines, specialities and cultures. Nemetic research

itself evolves by reproducing experiences of transliteracy in transmedia spaces.

NEMETICS RESEARCH ON TRANSMEDIA AND TRANSLITERACY

Context Analysis

In transmedia, the process is the product. Emerging experiences can be identified on the Internet by studying interaction sequences, exchange paths, and conversational structure, in augmented communication situations.

Nemetics should be understood as an ongoing process that is also a series of products. Context analysis becomes part of the production, and shows the internal process of collective debate and creation:

The power of transmedia is to make collaboration on even serious academic documents simple with almost no strain. No meetings. No phone calls. No schedules. Everyone works in their personal time. Inserts into any number of places. Goes away and waits for a response. (Josefowicz, 2015)

The International Nemetics Institutes provides a collaborative space for debating and exploring complexity from different scientific disciplines, by developing training and learning scenarios for hands-on problem solving in business, education and management fields. The main aim of this initiative is both process and product oriented. The process, begun in 2010, is an emergent intentional learning community that publishes blogs and social media posts, and performs open debates on twitter and other synchronic channels, offering the publication of a print newspaper and presentations in face-to-face training courses. The products include the founding of The International Nemetics Institute (TINI), based in Kolkata, India, and its subsidiary, The Nematic Institute of Art and Science (NIASK).

Case Study

The creation of the International Nemetics Institute is itself the result of collaborative interaction in the transmedia sphere with proactive intentions. The main aim was to provide a professional environment for Nemetics training and Nemetics community building. With a wide presence on the web, the International Nemetics Institute emerged from debates on Twitter, reflections on Google Plus forums, exchange of visual ideas in PowerPoint presentations, and dynamic groups of interest on LinkedIn. The Institute building process, in itself, is an example of collective transmedia emergence.

Overview

The process that led to the emergence of the Institute is best described by the term *synchrodipty* (Robertson, 2011), used to express the combination of synchronicity and serendipity that describes the starting sequence.

Main steps and key players:

- It was generated on the *Emergent by Design Blog*.

- It evolved into the Ebdish wiki (Michael Josefowicz, Daniel Durrant & Mark Frazier).
- Planning conversations emerged on twitter, under the hashtag #nemetics, with references to texts, images, sound, and videos.
- The dynamic conversations attracted international experts in Red Deer, Alberta, Canada (Sean Grainger), and Kolkata, India (Dibyendu De), Barcelona, Catalonia (Ray Gallon, Neus Lorenzo), and in Paris, France (Rotana Ty).
- Conversations expanded to Google Plus forums and LinkedIn groups.
- Mashups and image galleries are complementing textual discourse.
- Face to face meetings have taken place in different countries.
- Simultaneous conversations are flowing through different platforms, expanded into mind mapping, wave tank experiments, and 3D modeling.

Transmedia Environments

Nemetics presence can be tracked across several platforms and co-creation spaces:

- **Blog:** <http://rgbwaves.com/category/nemetics/>
- **YouTube Channel (TINI. The International NemeticsInstitute):** <http://www.youtube.com/channel/UCAes2xe3XVYTiaOyCCkdoTA>
- **Google Plus (+RapidInnovationOrg):** <https://plus.google.com/+RapidinnovationOrg/about>, ([+google.com/+NemeticsinstituteGlobal](https://plus.google.com/+NemeticsinstituteGlobal))
- **Twitter:** @NEMETICS
- **LinkedIn:** <https://www.linkedin.com/pub/international-nemetics-institute/84/14/3b3>
- **Collaborative Organization:** The Transformation Society, <http://www.transformationssociety.net/> publishing on Slideshare (<http://www.slideshare.net/TransformationSociety/presentations>) and on Twitter as @TransformSoc.

Different literacies are being developed in each one of these platforms, and across all of them, resulting in a new collaborative transliteracy.

Results: Analyzing the Behavior of Complex Creative Systems

The process has led to several results:

- From the transmedia debate, a research community has emerged and aggregated.
- The discipline of nemetics has been built across a network of connections, shaping an analytical tool set to engage wicked problems, such as the creation of an International Institute.
- A glossary of nemetic terms has been mapped to the nervous system, using a biomimicry model of communication in the tradition of memetics (Dawkins, 1989). Where a meme is a replicator in the cultural and cognitive context, equivalent to the gene in biology, the NEME is a replicator in the context of Complex Creative System (CCS).
- The same tools used to analyze the complexity of biology, are also used to analyze any other organic complexity. In nemetics, the model is the nervous system. Under this paradigm, a set of fractal analogies can be derived for studying transmedia co-creation and collective resonance:
 - The NEME is like a neuron. (In Transmedia it can be a shared idea, a closed dialogue, a formulated hypothesis...).
 - Bundles of NEMEs, called nemiStrings, are neural networks. (It can be an open debate, teamwork, group action, shared discussion...)
 - Bundles of nemiStrings are nemiTubes, like the nerve bundles found in the spinal column. (Communication exchanged in simultaneous discussions, joined teams from different

- platforms, augmented information management on several channels...)
- A nemiShape is the well-bounded interaction of the elements above, like the brain functioning within the skull. (It could be the community engaged in the same disciplinary debate, a social group sharing an aim, a formulated paradigm wherein debates can evolve).
- This structured landscape of neurons generates a complex creative system that is organically evolving, transforming, and reshaping itself, reproducing the recursive evolution of conversations, debates, and concept creation.
- Further results include mathematical representations of this complexity, diversification of narrative, and integration of meaning: mind maps, 3D animations, and visualized fragmented dialogues.

Current Hypothesis

Nemetics analysis provides a common code to researchers in different fields.

The recursive, fractal nature of NEME means that any level of complexity can be categorized as a NEME to clarify analysis. In a different discipline, for example, history, a singular event is a NEME at the level of events. Zooming in, the event devolves to vibrant nemiTubes of a diversity of social consequences, economic resonances, and cultural impacts. Following the fractal principle of self-similarity, an economic consequence is also a NEME on the level of analysis of consequences, and zooming in still further, consequences would have nemiTubes of market fluctuations and policies. In Geography, the metaphor can include trophic layers, like soil, plants, or animals (Provenza et al, 2013).

The concept of “narrative fractal” is transposed, in nemetics, as a “nemiPlex.” This nemiPlex is a complex of connected NEMEs that work the

way an enzyme works in biology, as a catalyzer of processes. The existence of a nemiPlex in the system catalyzes the process of the emergence of nemiStrings and nemiTubes. Importantly, a nemiPlex is strongest when it results from a diverse collaborative effort.

This is similar to what Lakoff refers to as a “metaphor” that facilitates an actor in “creating meaning.” The metaphor is an at-hand “explanation” for a new event (Lakoff, 2003). In nemetics a metaphor is seen as a constellation of concepts that are triggered by the need to interact (Exchange). It points to the fact that knowledge flows in networks of people while information resides in static web resources. Good transliteracy practice in a well-developed nemiPlex can speed up transmedia integration, for example, in High Performance Teams or Intentional Communities.

FUTURE RESEARCH DIRECTIONS

Nemetic Analysis of transmedia spaces helps understand the emerging communication systems in complex environments, and to design formal and informal transliteracy learning. Several action-reflection itineraries can be developed, in formal and informal training, for improved efficiency in identifying leadership, team dynamics, and coordination applied to transmedia communication. The main objective is social action.

Future benefits will come from applying results to personal and professional fields that are now emerging in the hybrid physical-digital environment:

- Interacting with wicked problems (favoring useful and valuable emergences from inherently chaotic systems)
- Designing and planning organizational action (using big data to adapt social behavior)
- Integrating gamification into professional fields (creating new transmedia spaces)

- Aggregating expanded connections and Internet of Things (new kinds of transliteracies)
- Relating personally and professionally to wearables and bionic implants (facing ethical and moral issues in collective debates)
- Developing lifelong learning environments (dynamizing and moderating MOOCs, eLearning platforms and mLearning communities)

These lines of research tend naturally towards the creation of a transformation society, where collaboration and self-emerging initiatives generate and explore transmedia learning environments.

CONCLUSION

Examples such as the creation of The International Nemetics Institute are useful to tell the story of transliteracy emergence and transmedia evolution and develop an academic corpus for integrating both transmedia and transliteracy into the communicative disciplines.

The increasing proliferation of communications platforms and modalities resulting from emerging technologies means that transmedia and transliteracy are going to become ever more important. Nemetics provides a simple model for understanding and integrating both transmedia contexts and transliteracy skills, and for working in complex adaptive/creative systems.

KEY TERMS AND DEFINITIONS

Intertext: A coherent text that shows a relationship to one or more other texts, where “text” is understood to mean any type of communicative content, typically forming a connected piece of work (includes images, sounds, video, etc.).

NEME: Mnemonic acronym for the fractal learning process of complex creative systems: Notice, Engage, Mull, Exchange.

Nemetics: A fractal code, evolved into a meta-language to facilitate communication among researchers in different disciplines in order to debate about complexity.

Synchrodipity: The compound interaction of synchronicity and serendipity, to produce a sense of discovery, delight, or well-being, and a sense of connectedness between people, ideas and actions,

derived from the flow and the interconnectivity of all things.

Transliteracy: The ability to read, write, and interact across a variety of communication tools, media, and platforms, from text, orality, signing, or drawing, through handwriting, print, TV, radio, and films to electronic networks and social media on digital platforms. It is a necessary complex skill for receiving, interiorizing or producing Transmedia.

Transmedia: Complex communication interaction based on multimedia, multimodal, multiplatform, intertextual human communication, in which each medium or platform has a distinct role to play in communicating the complete content. This interaction acquires meaning with each participating element by rebuilding the fragmented discourse.

Wicked Problem: A problem that is difficult or impossible to solve, because of incomplete, contradictory, and changing requirements that are difficult to define, identify, or recognize. It often involves stakeholders who have radically different worldviews. In addition, complex interdependencies make it so that the effort to solve one aspect of a wicked problem may reveal or create new problems.

Autonomic Cooperative Communications

N**Michał Wódczak***Samsung Electronics, Poland*

INTRODUCTION

Since the number of devices interconnected world-wide is growing at so unprecedented a pace, the orchestration of durable and resilient operation of networked systems becomes critically substantial. Especially when analysed in the context of network resiliency, such durability translates into the provision of key features of reliability, availability, safety, confidentiality, integrity, and maintainability. For this reason, it became highly valid to advocate for the integration of networking with the rationale behind autonomic computing in terms of self-configuration, self-optimisation, self-healing, and self-protection. This way the concept of Autonomic Cooperative Networking was proposed not only to integrate and capitalise on the above-mentioned building blocks, but, in particular, to incorporate the notion of Autonomic Cooperative Behaviour (Wódczak, 2014a). As such, stemming from and being triggered by the said Distributed Cooperative Relaying, the Autonomic Cooperative Behaviour intends to provide a mediation capability, not only aiming to facilitate cooperation among devices, but especially to integrate the relevant routines of the Optimised Link State Routing protocol. Consequently, the said devices are expected to share their computational capabilities and memory to perform joint data processing for the benefit of meeting the global performance indicators through increased resiliency.

As such, the paradigm of autonomic system design assumes that a networked system follow the operating principles of the Human Autonomic Nervous System and, thus, be able to self-manage without any external intervention. Yet, given the fact that autonomic designs are inherently char-

acterised by their own field of applicability, by no means should they be confused with the notion of autonomous or automated operation. In other words, while an autonomous development may, on the one hand, pertain to being stand-alone, and, on the other hand, to being cognitive, the concept of being automated is solely rooted in the operation of scripting. The difference in meaning does not exclude, however, certain dose of synergy so that autonomics could be supported through the inclusion of autonomous and automated routines. Following, to provide more details, the concept of Cooperative Relaying will be described on the basis of Virtual Antenna Arrays to pave the ground for the incorporation of Network Layer routines with special emphasis on the Optimised Link State Routing Protocol and its inherent Multi-Point Relay station selection heuristics. This way, such a routing enabled cooperation will be translated into Autonomic Cooperative Behaviour and integrated with the entities of the Generic Autonomic Network Architecture under the umbrella of Autonomic Cooperative Networked System design (Wódczak, 2014).

BACKGROUND

As the number of globally interconnected devices is becoming substantially large, the resulting networked systems are getting prone to configuration issues and resiliency becomes one of their key characteristics. Following the rationale behind self-management of autonomic computing, the main trend in networking nowadays is to put emphasis on the ability of a networked system to self-configure, self-optimize, self-heal, and self-protect without any explicit need for external

DOI: 10.4018/978-1-5225-2255-3.ch564

human intervention. This is crucial, for complexity reasons, as complete automation appears to be the only reasonable and justified way forward. In particular, devices may improve the related system robustness by sharing their computational resources through the application of cooperative schemes having been elevated to the level of Autonomic Cooperative Behaviour. For this reason the autonomic system design behind the Generic Autonomic Network Architecture was applied to synergise both the concept of Virtual Antenna Arrays and Multi-Point Relay station selection heuristics of the Optimised Link State Routing protocol, so that substantially large set-ups of devices could be considered to imitate the operation of Human Autonomic Nervous System. This was achieved with the aid of Autonomic Cooperative Networked System design allowing for the overall system to be controlled by Decision Making Entities within Autonomic Control Loops.

SYSTEM COMPONENTS

Cooperative Relaying

Cooperative relaying, also known as cooperative transmission, is undoubtedly one of the key advancements in the realm of mobile communications intended to facilitate the mitigation of the impairments induced and imposed by the characteristics of radio propagation (Pabst, Walke, Schultz, Herhold, Yanikomeroglu, Mukherjee, Viswanathan, Lott, Zirwas, Dohler, Aghvami, Falconer & Fettweis, 2004). Based on the assumption that Relay Nodes (RN) are to assist the process of transmission between the Source Node (SN) and the Destination Node (DN), this approach advocates that such a process be carried out in two phases. As outlined in Figure 1, during the first stage, both the DN and RN are assumed to receive the transmitted signal. Only after that may the RN additionally resend its copy towards the DN in order to, potentially, improve the transmission performance through the provision

of the so desirable diversity (Doppler, Redana, Wódczak, Rost & Wichman, 2009). In fact, there are a number of different variations of cooperative relaying known and this idea may also be referred to as cooperation diversity, cooperative diversity, or coded cooperation (Herhold, Zimmermann & Fettweis, 2004). In this work, however, the term of cooperative transmission is preferred as the most generic one (Wódczak, 2012).

Going further, based on the work described by (Laneman & Wornell, 2003) and according to the later classification given in (Herhold, Zimmermann & Fettweis, 2004), cooperative transmission schemes may be categorised either with regard to the forwarding strategy or protocol nature. Consequently, one may distinguish the amplify-and-forward, decode-and-forward, and decode-and-reencode categories. While the amplify-and-forward class is normally referred to as a non-regenerative approach, both its decode-and-forward and decode-and-reencode counterparts are typically named the regenerative ones (Herhold, Zimmermann & Fettweis, 2004). Additionally, the decode-and-reencode group may be subdivided even further to encompass fixed, adaptive, as well as feedback-based variations. One of the most comprehensive solutions of this type is known under the name of Virtual Antenna Arrays

Figure 1. Cooperative relaying

(VAAs) (Dohler, Lefranc & Aghvami, 2002), as such, being, most interestingly, usually perceived as complementary to Distributed Space-Time Block Coding (DSTBC) (Laneman & Wornell, 2003), where both the repetition-based and space-time coded cooperative diversity techniques may be practically applied (Alamouti, 1998), (Tarokh, Jafarkhani & Calderbank, 1999).

In particular, such a DSTBC-enabled and VAA-based system model may be clearly depicted as in Figure 2, where the process of transmission between the SN and DN comprises, once again, two phases. What is more, also during the first phase, the SN broadcasts its signal so that, fairly similarly, it is delivered to the DN, as well as the potential RNs. Following, upon correct reception, all the intermediate RNs process the received data and, eventually, resend it towards the DN, during the second phase. Yet, as it was already signalled, such a retransmission may be performed either in the repetition-based or space-time coded manner, thereby creating a completely new, added value. Moreover, one should also take into consideration that even though both these approaches are capable of achieving full spatial diversity, the space-time coded approach outperforms the repetition-based one, as it can be used more effectively for higher spectral efficiencies (Laneman & Wornell, 2003).

Figure 2. Virtual antenna array

This is why, despite the fact that there are different retransmission schemes readily applicable, as far as the second phase is concerned the described concept mostly capitalises on the idea of VAAs, where, most interestingly, the direct radio link between the SN and DN may not even exist (Wódczak, 2012).

Routing Protocol

The presented concept of Autonomic Cooperative Communications puts special emphasis on the integration of the commonly recognised Optimized Link State Routing (OLSR) protocol, being classified as a proactive solution. As such, not only does the Optimized Link State Routing protocol belong to so desirable a class of routing solutions, but it also employs the said Multi-Point Relay (MPR) station selection heuristics intended to reduce the control overhead understood as the number of messages broadcast for the purposes of accomplishing the task of network topology information dissemination (Clausen & Jacquet, 2003). Most generally, the idea is to transmit the so-called Topology Control (TC) messages exclusively through a set of selected neighbour nodes, chosen in such a manner that they belong to the one-hop neighbourhood of a given SN performing the task of broadcasting and have been chosen with utmost care and due diligence to cover the entire strict two-hop neighbourhood of that node. Such one-hop neighbours are recognised by means of Hello messages, which are naturally received by each of them, but cannot be retransmitted any farther.

As illustrated in Figure 3, the Source Node includes in its MPR set all the symmetric one-hop neighbours being the only ones to provide reachability to a particular two-hop neighbour residing in the strict symmetric two-hop neighbourhood of SN, and, additionally, always denoted as willing to carry and forward traffic (Jacquet, Muhlethaler, Clausen, Laouiti, Qayyum & Viennot, 2001). Following, should there still exist any uncovered two-hop neighbours of SN, the heuristics keeps

Figure 3. Multi-point relay station selection heuristics

being executed to select such a node in the one-hop neighbourhood which has not been inserted into the MPR set thus far and is characterised by the highest willingness to carry and forward traffic. In the event of the case that a multiple choice would hold, the one is selected which provides the highest reachability, i.e. through which the highest number of still uncovered two-hop neighbours may be reached. Otherwise, should it be impossible to select a single node, the node with the highest degree is chosen, where the degree of a one-hop neighbour denotes the number of its symmetric neighbours, excluding all the members of the one-hop neighbourhood and the SN performing the computation (Clausen & Jacquet, 2003).

In particular, as mentioned before, typical Relay Nodes may cooperate at Link Layer according to a more or less sophisticated scheme. However, the knowledge of such RNs about the network topology and the parameters of the separate radio links is solely limited to their closest one-hop neighbourhood. While it is still possible to imagine a more complex approach able to collect additional details at the said Link Layer, it seems a far better idea to utilise the information which is readily available at Network Layer instead. This

Figure 4. MPR-based VAA pre-selection

way the Routing information Enhanced Algorithm for Cooperative Transmission (REACT) was proposed which first removes each neighbour of the SN, characterised by a zero degree, from the one-hop neighbourhood, and executes the classic MPR heuristics iteratively over the set of one-hop neighbours until all the potential MPR nodes have been subdivided into the primary and additional MPR sets (Wódczak, 2012). In fact, each iteration results in a redundant MPR set, i.e. secondary, ternary and so on. Based on this, all the nodes are assigned to the most relevant VAAs being capable of providing cooperative connectivity between the SN and the DN, as depicted in Figure 4. The additional redundancy, in turn, may be utilised in the case of very sudden topology changes.

Autonomic Entities

For the needs of further integration with the Generic Autonomic Network Architecture, the concept of REACT, being in fact the key enabler for the fusion between MPR and VAA, was proposed to be translated into a more generic notion

of Autonomic Cooperative Behaviour (ACB) (Wódczak, 2014). Conceptually, such ACB stems directly from the OLSR protocol and it capitalises on the VAA-aided cooperative transmission scheme. However, from the general perspective, the above assumptions might be relaxed so that ACB would be agnostic to both the protocol class and cooperation type. On the other hand, the key element of the GANA architecture is the assumption of the existence of Decision Elements (DEs) at the Network Level, Node Level, Function Level, and Protocol Level (Chaparadza, Papavassiliou, Kastrinogiannis, Vigoureux, Dotaro, Davy, Quinn, Wódczak & Toth, 2009). This way each DE has its exclusive responsibilities and, at the same time, it is able to interact with other DEs. It means that, based on the control and monitoring information available within Autonomic Control Loops (ACL),

as depicted in Figure 5, each DE should be able to take its autonomic decisions which might be to some extent affected by the data it exchanges with its higher or lower level, peering or sibling counterparts.

For this reason, in order to instantiate the concept of Autonomic Cooperative Communications, it was primarily assumed that the definition of the Autonomic Node would need to be enhanced with the aforementioned rationale behind Autonomic Cooperative Behaviour, as outlined in Figure 6. This resulted directly in the introduction of the highly relevant Autonomic Cooperative Node intended to act as an enabler for cooperation among the Managed Entities, as orchestrated by their corresponding Decision Elements. In particular, the Generic Autonomic Network Architecture defines the aforementioned four levels of abstraction at

Figure 5. Autonomic control loop

which DEs may operate (Wódczak, 2012). Starting from the Protocol Level, there resides the Cooperative Processing Decision Element (CP_DE) which is responsible for controlling the aspects of cooperative transmission protocol requiring the cooperative computation of code words (Wódczak, 2011). The operation of CP_DE has to be aligned with the already existing Routing Management Decision Element (RM_DE), located at the Function Level, which needs to interact with its sibling DEs, so that the computation of the routing tables maintained at the cooperating devices could be properly synchronised (Wódczak, 2007).

Following, the RM_DE also needs to act pursuant to the directions from the other existing DEs, such as the Resilience and Survivability Decision Element (RS_DE) and the Fault Management Decision Element (FM_DE), both located at the Node Level and responsible for the provision of increased dependability (Wódczak, 2010). More specifically, the RS_DE alone is typically assumed to cover aspects of service resilience and survivability. At the same time, it is supposed to interact with its FM_DE counterpart which, in turn, controls the symptoms suggesting that a failure, for example, in terms of service continuity, may be imminent. Finally, while all these

DEs are located within Autonomic Cooperative Nodes, it is still necessary to provide substantial coordination at the Network Level. This task is accomplished with the aid of the Cooperative Re-Routing Decision Element (CR_DE), which is responsible for overseeing the system situation from a higher-level perspective (Wódczak, 2012). This way a comprehensive approach may be formed encompassing all the aforementioned components so necessary for the instantiation of Autonomic Cooperative Communications.

FUTURE RESEARCH DIRECTIONS

The evolution of autonomic cooperative networking appears to more and more emphasize the importance of the realm of computing itself, thus creating a new notion of autonomic cooperative computing enabled networked systems. In this respect, certain dose of further work is necessary, especially from the architectural perspective so that the fields of autonomic networking and computing may be fused very closely together, especially taking into account the ongoing standardisation efforts.

Figure 6. Architectural perspective

CONCLUSION

In this work the rationale behind the concept of Autonomic Cooperative Communications was detailed. First of all, the workings of Distributed Cooperative Relaying were outlined through the introduction of the idea of Virtual Antenna Arrays as an enabler for further analysis. Following, the incorporation of the relevant routines of the Network Layer was described which put special emphasis on the Optimised Link State Routing Protocol and its Multi-Point Relay selection heuristics. Finally, the Routing information Enhanced Cooperative Transmission was detailed as enabler for Autonomic Cooperative Behaviour, being tightly integrated with the entities of the Generic Autonomic Network Architecture.

KEY TERMS AND DEFINITIONS

Autonomic System: A concept advocating for a networked computer system to follow the principle behind the functioning of the Human Autonomic Nervous System, thus enabling it to self-manage without any need for external intervention for the majority of the time of its operation.

Distributed Cooperative Relaying: The mapping of the rationale behind spatio-temporal processing onto networked systems where designated Relay Nodes may form Virtual Antenna Arrays and, given proper synchronization, provide better transmission robustness or throughput.

Multi-Point Relays: A set of network nodes chosen with the aid of the MPR station selection heuristics of the Optimised Link State Routing protocol in such a way that the protocol control overhead becomes substantially reduced.

Spatio-Temporal Processing: A generic term for the space-time block and trellis coded concepts allowing for the exploitation of the radio channel orthogonality for the purposes of increasing either the system robustness or its throughput with the aid of the Multiple Input Multiple Output (MIMO) technology.

Clique Size and Centrality Metrics for Analysis of Real-World Network Graphs

N

Natarajan Meghanathan
Jackson State University, USA

INTRODUCTION

Network Science is a fast-growing discipline in academics and industry. It is the science of analyzing and visualizing complex real-world networks using graph theoretic principles. Several metrics are used to analyze the characteristics of the real-world network graphs; among them “centrality” is a commonly used metric. The centrality of a node is a measure of the topological importance of the node with respect to the other nodes in the network (Newman, 2010). It is purely a link-statistics based measure and not based on any offline information (such as reputation of the node, cost of the node, etc). The commonly used centrality metrics are degree centrality, eigenvector centrality, closeness centrality and betweenness centrality. Degree centrality (DegC) of a node is simply the number of immediate neighbors for the node in the network. The eigenvector centrality (EVC) of a node is a measure of the degree of the node as well as the degree of its neighbor nodes. We refer to DegC and EVC as degree-based centrality metrics. Closeness centrality (CIC) of a node is the inverse of the sum of the shortest path distances of the node to every other node in the network. Betweenness centrality (BWC) of a node is the ratio of the number of shortest paths the node is part of for any source-destination node pair in the network, summed over all possible source-destination pairs that do not involve the particular node. We refer to CIC and BWC as shortest path-based centrality metrics. Computationally efficient polynomial-time algorithms have been proposed in the literature (Brandes, 2001; Strang, 2005; Cormen et. al., 2009; New-

man, 2010) to determine exact values for each of the above centrality metrics; hence we categorize centrality as a computationally lightweight metric.

A “clique” is a complete sub graph of a graph (i.e., all the nodes that are part of the sub graph are directly connected to each other). Cliques are used as the basis to identify closely-knit communities in a network as part of studies on homophily and diffusion. Unfortunately, the problem of finding the maximum-sized clique in a graph is an NP-hard problem (Cormen et. al., 2009), prompting several exact algorithms and heuristics to be proposed in the literature (Pattabiraman et. al., 2013; Fortunato, 2010; Palla et. al., 2005; Sadi et. al., 2010; Tomita & Seki, 2003). In this chapter, we choose a recently proposed exact algorithm (Pattabiraman et. al., 2013) to determine the size of the maximum clique for large-scale complex network graphs and extend it to determine the size of the maximal clique that a particular node is part of. We define the maximal clique size for a node as the size of the largest clique (in terms of the number of constituent nodes) the node is part of. Note that the maximal clique for a node need not be the maximum clique for the entire network graph; but, the maximum clique for the entire graph could be the maximal clique for one or more nodes in the network.

Since the maximal clique size problem is a computationally hard problem and exact algorithms run significantly slower on large network graphs, our goal in this chapter is to explore whether the maximal clique size correlates well to one of the commonly studied computationally lightweight metrics, viz., centrality of the vertices, for complex real-world network graphs: if we observe a

DOI: 10.4018/978-1-5225-2255-3.ch565

high positive correlation between maximal clique size and one or more centrality metrics, we could then infer the ranking of the vertices based on the centrality values as the ranking of the vertices based on the maximal clique size in real-world network graphs. Ours will be the first chapter to conduct a correlation study between centrality and maximal clique size for real-world network graphs. To the best of our knowledge, we did not come across such a work that has done correlation study between these two metrics (and in general, a computationally hard metric vis-a-vis a computationally lightweight metric) for real-world network graphs. Throughout the chapter, we use the terms ‘node’ and ‘vertex’ as well as ‘link’ and ‘edge’ interchangeably. They mean the same.

Background

To the best of our knowledge, ours is the first work to focus on a correlation coefficient analysis between a computationally hard metric (maximal clique size for the individual vertices) with that of a computationally lightweight metric (centrality values of individual vertices) for complex real-world network graphs. The work available in the literature so far considers these two metrics separately. Recently, Li et al (2014) conducted a correlation coefficient analysis study among the centrality metrics for real-world network graphs. Centrality metrics have been widely studied for analysis and visualization of complex networks in several domains, ranging from biological networks to social networks (e.g., Koschutski & Schreiber, 2008; Opsahl et. al., 2010). The research focus with regards to cliques in the context of complex networks is to come up with efficient heuristics to reduce the run-time complexity in determining the maximum size clique for the entire network graph. Though branch-and-bound has been the common theme among these works, the variation is in the approach used to arrive at the bounds and enforce them in the search space. Strategies used for pruning the search space are typically based on node degree (e.g., Pattabiraman et. al.,

2013), vertex ordering (e.g., Carraghan & Pardalos, 1990) and vertex coloring (e.g., Ostergard, 2002). Recently, a parallelized approach (Rossi et. al., 2014) for branch and bound has also been proposed for determining cliques in real-world networks ranging from 1000 to 100 million nodes. Nevertheless, none of the research so far has focused on identifying correlation between the maximal clique size for an individual vertex (the size of the largest clique that a particular vertex is part of) with any of the commonly studied metrics (like centrality) for network analysis. Ours is the first step in this direction. With the problem of determining maximum size clique for the entire network graph and maximal size cliques for the individual vertices being NP-hard and computationally time-consuming for complex real-world networks of larger size, it becomes imperative to analyze the correlations of the maximal clique size values of the individual vertices to that of the network metrics that can be easily computed so that meaningful inferences about maximal clique size values can be made.

Centrality Metrics

This section discusses the four centrality metrics that are studied in this chapter. The highest ranked vertex or set of vertices with respect to each of the centrality metrics is shown shaded in the graphs of these figures. The degree centrality (DegC) of a vertex is the number of neighbors adjacent to it (example illustrated in Figure 1). Eigenvector centrality (EVC) of a vertex is a measure of the degree of the vertex as well as the degree of its neighbors. EVC of the vertices in a graph (example illustrated in Figure 2) are the entries in the principal eigenvector of the adjacency matrix for the graph. The larger the value of the entry for an vertex in the principal eigenvector, the higher is its ranking with respect to EVC. The principal eigenvector is determined by running the power-iteration algorithm (Strang, 2005) on the adjacency matrix of the network graph. The closeness centrality (CIC) of a vertex is the inverse

Figure 1. Example to illustrate the computation of degree centrality

of the sum of shortest path distances from the vertex to every other vertex (example illustrated in Figure 3). Betweenness centrality (BWC) is a measure of how significant a node is in facilitating communication between any two nodes in the network. The betweenness centrality for a node is the ratio of the number of shortest paths a node is part of for any source-destination node pair in the network, summed over all possible source-destination pairs that do not involve the particular node (example illustrated in Figure 4).

From Figure 1-4, we notice that the betweenness centrality-based ranking of the vertices is different from the degree centrality and eigenvector centrality-based ranking of the vertices. The degree and EVC-centralities take into consideration only the degree of the vertices and they are positively correlated. However, the BWC centrality takes into consideration the contribution of a vertex in facilitating communication between any two vertices in the network on the shortest path; such vertices are likely to be more central to the

Figure 2. Example to illustrate the calculation of eigenvector centrality using power iteration method

Figure 3. Example to illustrate the calculation of closeness centrality

network and form the backbone or the core of the network. As can be seen in the example run of Figure 4, vertex 4 that was ranked lower with respect to degree and Eigenvector centrality is ranked the highest (along with vertex 3) with respect to Betweenness centrality. Also note that in this example graph, no source-destination pair need to go through vertices 1 or 6 or 7 on a short-

est path. As a result, the betweenness centrality for each of these three vertices (1, 6 and 7) is 0.

CLIQUE

A clique is a sub graph of a graph in which all the vertices are adjacent to each other. The problems

Figure 4. Example to illustrate the calculation of betweenness centrality

of finding maximum size clique for the entire graph as well as the maximal size cliques for the individual nodes are NP-hard problems (Cormen et. al., 2009). Several exact algorithms (that at the worst case incur exponential time for a NP-hard problem) have been proposed to determine maximum size cliques for sparse graphs. Recently, with the surge in interest to analyze large real-world networks from a graph theoretic point of view, researchers have proposed efficient exact algorithms (e.g., Tomita & Seki, 2003; Palla et. al., 2005; Fortunato, 2010; Sadi et. al., 2010; Pattabiraman et. al., 2013) to determine maximum size cliques for large/dense graphs. The common theme (Ostergard, 2002) behind these algorithms is a branch and bound approach of searching through all possible candidate cliques and limiting the search to only viable candidate sets of vertices whose agglomeration has scope of being a clique of size larger than the currently known clique found as part of the search; the variation among these exact algorithms is the pruning strategy (the approach taken to compute the bounds and use them) to limit the search. In this section, we will describe one such branch and bound-technique based exact algorithm that has been recently proposed in the literature (Pattabiraman et. al., 2013) to determine maximum size clique in large network graphs and explain our modification to the algorithm so that it can be used to determine the maximal cliques that each vertex in the graph

is part of; the largest among these cliques is the maximum size clique for the entire graph.

Figure 5 outlines the pseudo code of the algorithm, proposed originally by Pattabiraman et al (2013), to determine the maximum size clique for an entire graph. The procedure MAXCLIQUE proceeds in iterations, with each iteration designed to determine the maximum size clique for the entire graph that could also include vertex v_i (considered in the increasing order of the IDs). The sub routine CLIQUE called with vertex v_i as the first constituent vertex of the largest possible clique involving v_i , expands with one vertex at a time through a combination of iterations and recursions. During the sequence of returns from the recursive calls, it is possible that a new sequence of recursions and iterations is triggered due to the presence of a neighbor u of v_i that has scope for being in a clique (involving v_i) of size larger than the clique found so far for the entire graph. The algorithm explores all such possible cliques involving vertex v_i that have scope for exceeding the currently known maximum size clique for the entire graph.

At the end, the algorithm returns the maximum size clique for the entire graph that also happens to be the maximal size clique involving some vertex v_i such that there is no other vertex v_j ($i > j$) that is also part of the clique. Since the algorithm proceeds with vertices in the increasing order of their IDs, if the maximum size clique for the entire

```

Procedure MAXCLIQUE ( $G = (V, E)$ )
   $max \leftarrow 0$ 
  for  $i : 1$  to  $|V|$  do
    if  $\text{degree}(v_i) \geq max$  then
       $U \leftarrow \phi$ 
      for each  $v_j \in \text{Neighbor}(v_i)$  do
        if  $\text{degree}(v_j) \geq max$  then
           $U \leftarrow U \cup \{v_j\}$ 
      CLIQUE( $G, U, 1$ )

Subroutine CLIQUE( $G = (V, E), U, size$ )
  //  $size$  is the size of clique found so far
  if  $U = \phi$  then
    if  $size > max$  then
       $max \leftarrow size$ 
    return
  while  $|U| > 0$  do
    if  $size + |U| \leq max$  then
      return
    select any vertex  $u$  from  $U$ 
     $U \leftarrow U \setminus \{u\}$ 
     $N(u) := \{w \mid w \in \text{Neighbor}(u) \wedge \text{degree}(u) \geq max\}$ 
    Clique( $G, U \cup N(u), size + 1$ )

```

graph involves at least one vertex v_i with a smaller ID, the presence of the maximum size clique is detected much earlier and the subsequent iterations (with vertices whose IDs are greater than v_i , but could be part of only cliques of size smaller or equal to the maximum size clique of the entire graph involving v_i) are merely pruned, contributing to the time-efficiency of the algorithm. Hence, the labeling of the vertices with their IDs plays a significant role in the run-time complexity of the algorithm; the algorithm is capable of quickly determining the maximum size clique if the latter comprises of at least one vertex with a smaller ID.

Figure 6 illustrates our modifications (to determine the size of the maximal clique that each vertex is part of) to the pseudo code of the algorithm presented in Figure 5. The tradeoff is an increase in the run-time of the algorithm: we cannot just prune our search based on the vertex IDs; we have to explore the neighborhood of each of the vertices to determine the maximal size clique that each vertex is part of. Since to start with, the maximal size clique known for vertex v_i is 0, there is no need to filter the neighbors of v_i in procedure MAXIMALCLIQUE based on the degree of the neighbors; all neighbors of v_i are included in the set U and passed onto the

sub routine CLIQUE. However, we could retain all of the pruning steps in sub routine CLIQUE (called to find the maximal size clique for each of the vertices v_i) and recursive calls to the same: there is no need to explore the neighbors of vertex u whose degree is less than that of the currently known maximal clique size for vertex v_i .

REAL-WORLD NETWORK GRAPHS AND CORRELATION STUDIES

The network graphs analyzed are briefly described as follows: (i) *Zachary's Karate Club* (Zachary, 1977): Social network of friendships (78 edges) between 34 members of a karate club at a US university in the 1970s; (ii) *Dolphins' Social Network* (Lusseau et. al., 2003): An undirected social network of frequent associations (159 edges) between 62 dolphins in a community living off Doubtful Sound, New Zealand; (iii) *US Politics Books Network* (Krebs, 2008): Nodes represent a total of 105 books about US politics sold by the online bookseller Amazon.com. A total of 441 edges represent frequent co-purchasing of books by the same buyers, as indicated by the “customers who bought this book also bought these other

books” feature on Amazon; (iv) *WordAdjacencies Network* (Newman, 2006): This is a word co-appearance network representing adjacencies of common adjective and noun in the novel “David Copperfield” by Charles Dickens. A total of 112 nodes represent the most commonly occurring adjectives and nouns in the book. A total of 425 edges connect any pair of words that occur in adjacent position in the text of the book; (v) *US College Football Network* (Girvan & Newman, 2002): Network represents the teams that played in the Fall 2000 season of the American Football games and their previous rivalry - nodes (115 nodes) are college teams and there is an edge (613 edges) between two nodes if and only if the corresponding teams have competed against each other earlier; (vi) *US Airports 1997 Network*: A network of 332 airports in the United States (as of year 1997) wherein the vertices are the airports and two airports are connected with an edge (a total of 2126 edges) if there is at least one direct

flight between them in both the directions. Data for networks (i) through (v) can be obtained from <http://www-personal.umich.edu/~mejn/netdata/>. Data for network (vi) can be obtained from: <http://vlado.fmf.uni-lj.si/pub/networks/pajek/data/gphs.htm>.

The spectral radius degree ratio is a measure of the variation in the node degree with respect to the average node degree; the closer the ratio is to 1, the smaller the variations in the node degree and the degrees of the vertices are closer to the average node degree (characteristic of random graph networks). The farther is the ratio from 1, the larger the variations in the node degree (characteristic of scale-free networks). Figure 7 presents the degree distribution of the network graphs in the increasing order of their spectral radius ratio for node degree (1.01 to 3.23).

Table 1 presents a correlation coefficient analysis of the four centrality metrics and the maximal clique size observed for the vertices in

Table 1. Correlation between centrality metrics and maximal clique size for the nodes

Network Index	Network Name (Increasing Order of Spectral Radius Ratio)	Degree vs. Clique	Eigenvector vs. Clique	Closeness vs. Clique	Betweenness vs. Clique
(v)	US College Football Network	0.315	0.348	-0.028	-0.168
(ii)	Dolphins' Social Network	0.776	0.563	0.418	0.277
(iii)	US Politics Books Network	0.701	0.747	0.321	0.367
(i)	Zachary's Karate Network	0.641	0.767	0.615	0.458
(iv)	Word Adjacencies Network	0.706	0.815	0.835	0.478
(vi)	US Airports 1997 Network	0.868	0.953	0.843	0.404

each of the six real-world network graphs studied in this chapter. Values of correlation coefficient greater than or equal to 0.8 (high correlation) have been highlighted in yellow; values below 0.5 (low correlation) are highlighted in light blue; and values between 0.5 and 0.8 (moderate correlation) are not highlighted in any color. If $\bar{X}$ and $\bar{Y}$ are the average values of the two metrics (say X and Y) observed for the vertices (IDs 1 to n , where n is the number of vertices) in the network, the formula used to compute the Correlation Coefficient between two metrics X and Y is as follows:

$$\begin{aligned}
 & \text{Corr Coeff}(X, Y) \\
 &= \frac{\sum_{ID=1}^n (X[ID] - \bar{X}) * (Y[ID] - \bar{Y})}{\sqrt{\sum_{ID=1}^n (X[ID] - \bar{X})^2} \sqrt{\sum_{ID=1}^n (Y[ID] - \bar{Y})^2}}
 \end{aligned}$$

As we can see in Table 1, in general, the correlation between the centrality metrics and the maximal clique size increases as the spectral radius ratio for node degree increases. This implies, the more scale-free a real-world network is, the higher the correlation between the centrality value and the maximal clique size observed for a node. With several of the real-world networks being mostly scale-free, we expect these networks to exhibit a similar correlation to that observed in this chapter. The visualization figures presented in the chapter were obtained by porting the network data as well as the centrality/maximal clique size results to Gephi (Cherven, 2013) and making appropriate changes to the settings in the latter. The layout algorithm chosen in Gephi for visualization is the Fruchterman Reingold algorithm (Fruchterman & Reingold, 1991) that presents the network in a circular format (like a globe).

Figure 8. US College Football Network: Correlation of maximal clique size with centrality

Figure 11. Zachary's Karate Club Network: Correlation of maximal clique size with centrality

Figure 12. Word Adjacencies Network: Correlation of maximal clique size with centrality

Figure 13. US Airports (1997) Network: Correlation of maximal clique size with centrality

Figures 8-13 depict the correlation observed for the four centrality metrics with that of the maximal clique size for the vertices in the real-world network graphs. In these figures, the node size is a measure of the node centrality (the larger a node is, the larger is its centrality value); the node color is a measure of the maximal size clique the vertex is part of (the darker a node is, the larger is the size of the maximal clique for the node). Among the two classes of centrality metrics, we observe the degree-based centrality metrics (degree centrality and eigenvector centrality) to be very positively and highly correlated with the maximal clique size observed for the nodes. Between the two degree-based centrality metrics, the eigenvector centrality metric shows higher positive correlations to the maximal clique size. This could be attributed to the eigenvector centrality of a node being a measure of both the degree of the node as well as the degrees of its neighbors. That is, a node with high degree as well as located in a neighborhood of high degree vertices is more likely to be part of a maximal clique of larger size. In addition, as the networks get increasingly scale-free, nodes with high degree are more likely connected to other similar nodes with high degree to facilitate an average path length that is almost independent of network size: characteristic of scale-free networks (Newman, 2010), contributing to a positive correlation between degree-based centrality metrics and maximal clique size.

With respect to the two shortest-path based centrality metrics, the betweenness centrality

metric is observed to exhibit a low correlation with maximal clique size for all the six real-world network graphs; the correlation coefficient increases as the network becomes increasingly scale-free. In networks with minimal variation in node degree (like the US College Football network that is more closer to a random network), nodes that facilitate shortest-path communication between several node pairs in the network are not part of a larger size clique; on the other hand, nodes that are part of larger size cliques in such random networks exhibit a relatively lower betweenness centrality. Since the degrees of the vertices in random networks are quite comparable to the average node degree, there is no clear ranking of the vertices based on the degree-based centrality metrics and maximal size cliques that they are part of. Also, if at all a vertex ends up being a larger sized clique in random network graphs, it does not facilitate shortest path communication between the majority of the vertices (contributing to a negative/zero correlation or at best a low correlation with betweenness centrality). As the network becomes increasingly scale-free, the hubs that facilitate shortest-path communication between any two nodes in the network exhibit higher betweenness and closeness centralities as well as form a clique with other high-degree hubs - exhibiting the ultra small-world property; the average path length is $\ln(\ln N)$, where N is the number of nodes in the network (Newman, 2010). The correlation of the closeness centrality values and the maximal clique size values observed for the vertices in

real-world network graphs is significantly higher (i.e., positive correlation) for networks that are increasingly scale-free.

Overall, the degree-based centrality metrics exhibit a relatively better correlation with the maximal clique size compared to that of the shortest-path based centrality metrics (especially in networks with low-moderate variation in node degree). For real-world networks that exhibit moderate-high variation in node degree, the shortest-path based centrality metrics (especially closeness centrality) fast catch up with that of the degree-based centrality metrics and exhibit higher levels of positive correlation with maximal clique size. We anticipate that as the networks become increasingly scale-free, the hubs (that facilitate shortest-path communication between any two nodes) are more likely to form the maximum clique for the entire network graph - contributing to higher levels of positive correlation between any of the four centrality metrics and maximal clique size.

FUTURE RESEARCH DIRECTIONS

With the problem of determining maximal clique sizes for individual vertices being computationally time consuming, our approach taken in this chapter to study the correlation between maximal clique sizes to centrality can be the first step in identifying positive correlation between cliques/ clique size in real-world network graphs to one or more network metrics (like centrality) that can be quickly determined and henceforth appropriate inferences can be made about the maximal size cliques of the individual vertices. We observe the degree-based centrality metrics (especially the eigenvector centrality) to show promising positive correlations to that of maximal clique sizes of the individual vertices, especially as the networks get increasingly scale-free; this observation could form the basis of future research for centrality-clique analysis for complex real-world networks.

CONCLUSION

The correlation coefficient analysis studies between the four centrality metrics (degree, eigenvector, betweenness and closeness centralities) and the maximal clique size for the vertices in the real-world network graphs illustrate several significant findings that have been so far not reported in the literature: (i) the degree-based centrality metrics (especially the eigenvector centrality) exhibit a significantly high positive correlation to the maximal clique size as the networks get increasingly scale-free; (ii) the betweenness centrality of the vertices exhibits a low correlation with that of the maximal size cliques the vertices can be part of; (iii) in real-world networks that are close to random network graphs, the centrality metrics exhibit a low correlation to maximal clique size (especially in the case of shortest-path based closeness and betweenness centrality metrics); (iv) for all the four centrality metrics, the extent of positive correlation with maximal clique size increases as the real-world networks become increasingly scale-free.

KEY TERMS AND DEFINITIONS

Algorithm: A sequence of steps to perform a particular task.

Betweenness Centrality: A measure of the fraction of shortest paths between any two vertices that go through a vertex, considered over all pairs of vertices excluding the vertex.

Branch and Bound: An algorithmic strategy that prunes the search space and explores only candidate solutions that have the potential to be better than the currently known solution.

Centrality: A quantitative measure of ranking the vertices of a graph based on its topological structure.

Clique: A sub graph of a graph such that there is an edge between any two vertices.

Clique Size: The size (number of vertices) of the largest clique a vertex is part of.

Closeness Centrality: A measure of the sum of the lengths of the shortest paths from a vertex to the rest of the vertices.

Computationally Lightweight Metric: A network metric whose computation is not time consuming.

Correlation: A statistical dependence between two variables or sets of data.

Degree Centrality: A measure of the number of adjacent neighbors of a vertex.

Eigenvector Centrality: A measure of the degree of a vertex as well as the degree of its neighbors.

Random Network: A network whose degree distribution follows a Poisson pattern wherein the degree of all the vertices lies close to the average degree and the probability of finding a vertex with a degree much farther away from the average degree is zero.

Spectral Radius: The largest Eigenvalue of the adjacency matrix of a graph.

Scale-Free Network: A network whose degree distribution follows a power-law pattern wherein a majority of the vertices have a smaller degree,

but there exists a non-zero probability for finding a vertex with a relatively much larger degree.

Small-World Property: A characteristic property of complex networks wherein the number of hops on the shortest paths between any two vertices is at most the logarithm of the number of vertices in the network.

Topology: An arrangement of the nodes in the network that can be used for communication between any two nodes in the network.

INTRODUCTION

A Wireless Sensor Network (WSN) is composed of a set of hundreds of devices deployed in a common area, which are connected among them. Each device has the same capabilities; it is able to collect information from the surrounding environment through one or more sensors, process this information in a local manner. Data collection is usually made by a sink node or base station. A WSN can be used to control multiple tasks in one environment; the sensors require of data sensed from multiple sources by delivering information to multiple sinks at the same time.

There are a wide variety of current research problems in this area, such as tracking, surveillance, military applications, building automation, disaster management, and agriculture, among others. The applications are designed to obtain precise information from the environment regardless of the human presence. Radio communication, processing, transmission/reception generally are the main cause of power consumption. A multi-sink approach is becoming an efficient scheme to reduce the energy consumption in the whole network, either in a centralized or distributed application. In this paper, distributed techniques are presented and analysed.

The analysis is focused on the used strategies in a multiple sink environment, whether the nodes are static or mobile and how applications can be

improved by mixing more than one strategy; the objective of the application such as event detection, following a target, finding the best route, collecting and data aggregation, among others. The survey covers recent and traditional works and presents a discussion of their advantages and drawbacks. A simple and operational distributed algorithm that performs network formation and data collection using a multi-sink environment is presented.

This article is organized as follows: the next section presents the generalities and features of WSNs. The third section presents a classification of distributed approaches based on multi-sink environments; the fourth section describes the classification of the related works and discusses their proposals. The fifth section focuses on the simple and operational proposal of a distributed and multi-sink protocol for a WSN; finally, the last section presents the concluding remarks, which drive further research in the area.

BACKGROUND

Wireless Sensor Networks

Wireless Sensor networks with a single sink node have constraints; one of them is presented during the data collection, where bottleneck (Hochbaum & Shmoys, 1986) and hotspot problems (Sungjin

& Kim, 2006) can arise. Another limiting factor emerges when the purpose of the application is finding a target and the sink is far away from it; in this case, the routing can require great expenses of energy. Another drawbacks are presented when the sink require of responses in a short period of time and the routing is not efficient, when the sink node is not available, or there is a high demand for transmissions and one sink is not enough.

Multi-sink platforms have arisen as response to this kind of problems; a multi-sink platform provides redundancy, avoids problems in the data collections and increases the efficiency of the application. A set of sinks can be strategically or randomly distributed in the coverage area to collect and process the information from the environment. The sink or sinks can be static or mobile according to the available resources of the application.

Once the topology strategy is specified, the information can be collected following a distributed or centralized policy via multi-hop mode. In this article, we focus on the distributed strategies. *Distributed techniques* allow to the nodes take their own decisions in a locally way and dispense the information to a limited set of neighbours nodes within a scope area, which provide energy savings and spreading the information in a uniform manner to avoid the overhearing or hot spot problems. The flexibility of distributed systems

enables targeting random environments without complications during the information collection.

A WSN aims to gather environmental data, the node devices placement may be known or unknown a priori. Network nodes can have a *driven* (IP communication) or *logical* communication (topological communication defined by users or by the application) with all devices; such communication defines the topology according to the application. The logical topology is mainly defined based on the nodes communication. It can be either ad-hoc or strategy based (self-organization, clustering, pheromone tracking, and so on) (Carlos-Mancilla et al. 2016).

Certainly, one of the most important advances in the current proposals has been the *self-organization* (SO) approach in which the nodes are considered autonomous; they interact with the neighbour nodes and are independent of the information of the rest of the nodes. The aim is to achieve collective tasks that exceed its individual capabilities. Examples of these techniques are found in nature (insect colonies, biological cells, the flock of birds, the foraging behaviour of ants, etc.) (Mamei et al., 2006), (Schmeck et al., 2010). Finally, distributed multi-sink approaches support large density scenarios without compromising the network performance. In Table 1 a summary of the main features considered in distributed and centralized multi-sink applications is presented.

Table 1. Metrics in multi-sink applications

Metrics	Centralized	Distributed
Large scale	It is not applicable in big scale networks; the handled information is high.	The handled information is within a range of transmission; small or large ranges do not affect the performance of the network.
Routing	It can be efficient for small networks.	The routing is fast for the amount of information managed.
Energy saving	The number of transmissions and receptions needed to refresh the whole network is expensive.	It is low for transmissions, receptions, and notification of changes in the network.
Redundancy	It is good when there is a failure shown in the system.	According to the application, the redundancy can be faced in an efficient manner.
Reconfiguration	It is expensive spreading the changes to the whole network	The reconfiguration accuracy depends on the application.

CLASSIFICATION OF MULTI-SINK TECHNIQUES

Distributed Multi-Sink Applications (DMSA) have been characterized to be one of the robust and reliable techniques in wireless sensor networks. In such techniques, every node is responsible for providing operation, such as event detection, routing, topology formation, sensing, data collection, and information processing according to the available information in their coverable area. Distributed and multi-sink techniques together allows increasing the efficiency of a network. Multiple sink environments are classified according to the support operation of the nodes in the network, either *mobile* or *static*. Besides, a subdivision of both techniques can also be made *by the application*, and the *technique* used during any procedure. The taxonomy of the classification is shown in Figure 1.

The subclass *By application* in both cases static and mobile can be divided into the main research of any application, such as *Routing*, *Event*

target, and *DA & DC* (Data Aggregation and Data Collection). Whereas the *Technique* subclass is divided into *Clustering*, *Tree formation*, and *SO* approaches. Hybrid approaches can appear to improve an application. An explanation in detail of this classification, protocols, and techniques are reviewed in next section.

DISTRIBUTED APPROACHES USING MULTI-SINK ENVIRONMENTS

Distributed protocols in wireless sensor networks must provide a reduction in the energy consumption, robustness, and reliability algorithms despite the limited energy, noise, loss of messages, and obstacles.

Recently, many works focus on reducing the energy consumption, minimising the number of hops, providing robustness to the network, increasing the throughput, and so on. However, a route with the minimum number of hops may not always be the optimal and reliable route. A

Figure 1. Taxonomy of the multi-sink environments

network with a large number of devices is not always the best option, or even minimising the number of transmissions can have adverse effects. For the above reasons, according to the nature of the application, it is important to define the set of metrics, constraints, and features to evaluate the performance of a network (Muhammad et al., 2015).

In this chapter, we propose a classification and discuss relevant research works included in every one of them. A work can be included in more than one classification and they are focused in distributed multi-sink environment using diverse strategies.

Application Oriented

An application is defined by the available resources and the environment where the devices will be deployed. According to the application, the nodes have an assigned task; every task of a node has a main purpose such as finding the best available route, discovery a specific target, collect data, etc., in order to reduce the energy consumption, prolong the lifetime, generate a robust network or reducing the use of the resources.

We consider that the available applications can be classified into three categories: *Routing*, *Event target*, and *Data Aggregation & Data Collection* (DA & DC).

Routing

Routing is a process that selects the best route available in a defined environment, in a common area or using a specific number of nodes. The route is determined based on different metrics such as evaluating the number of hops to get to the nearest sink node, the minimum distance between the nodes, the weight of the nodes, the residual energy, the number of visited nodes, and so on. This is shown in Figure 2.

For instance, a tolerance control for enhancing a wireless sensor network using a multi-sink environment is presented in (Huang, 2010). In this work a tolerance area is defined; the nodes out of this area select the shortest path to route their data from source nodes to the nearest sinks. The sensor nodes in this area might switch to different paths to balance the load of sensors in the heavy area. Sensors are deployed uniformly in the network. Sensors outside the area, which are enough close to the area, such that the distance is less than a

Figure 2. Routing process

threshold τ , are considered as located in the area. The properly enlargement of the tolerance area would enhance effectively the data delivery rate.

Drawbacks of this approach appear when the loading of sensors in the network is not balanced; thus, sensors sometimes should select a candidate route to bypass the sensors with too much load or low battery level. The data rate decrease with few sink nodes and the energy depletion is high when looking for alternative routes based on the tolerance area.

An energy conserving dynamic routing with heterogeneous sensor networks is presented in (Lin, 2010); the authors present a fully distributed routing algorithm to support large scale networks based on the Bellman-Ford algorithm (Sedgewick, 2015) for routing. Two kinds of sensors are used; a large number of *L-sensor* which is powered by batteries with limited energy and communication capacity, and several *H-sensor* that serve as sink node with significantly higher computing power and communication capability. It is assumed that *L*-nodes only dissipate energy in data transmission.

The routing exploration is based on the broadcasting method and the nodes build a routing table. Every *L-sensor* receive its neighbours' routing messages, computes a new PBEC value, and broadcasts its updated routing information if the PBEC (Path Bottleneck Energy Cost) value is changed. This paper presents a significant improvement compared with two centralized methods. The energy cost for discovering a neighbourhood is not considered and the cost for data broadcasting method is expensive. The authors do not take into account reconfiguration and data seems to be forwarded always following the same route. This proposal also belongs to the tree formation classification.

Another proposal based on the formation of the clusters and routing is presented in (Xu, 2012); this paper is focused on the reduction of the energy consumption during the cluster formation and submitting information; explained in a posterior section.

A routing protocol to balance the loads in the network with multiple sinks to prolong the lifetime of the system is presented in (Zhang, 2015). After a children node generates or receives a packet, it randomly chooses a parent node using a probability list and takes the chosen node as the next-hop destination of the packet.

The sinks select one of them to be the head sink, which serves as an arbitrator. The arbitrator sinks decide the assignment of nodes to sinks belong based on two criteria: the hop number and the number of nodes of the sinks. In some situations, the tree structure cannot guarantee the balancing of the loads, some collisions can appear, and messages can be lost. Data aggregation is not considered.

An intelligent Agent-based Routing protocol that provides data delivering to mobile sinks is presented in (Kim, 2010). The communication with the agents is performed through a broadcasting method. In this protocol the messages can be lost during the data collection process and does not support channel variability. The energy consumption is also related to the source data rate, which is independent of the protocol.

Event Target

This kind of strategies is used when the nodes in the environment look for a specific node, a target, or a specific area for sensing in the environment. Figure 3 presents an example of an event target network; once the nodes detect an event, they send the information to the nearest sink node.

For instance, a virtual infrastructure based on honeycomb tessellation for data dissemination is presented in (A. T. Erman, 2012). This work can be classified as a routing or event target proposal.

The virtual infrastructures support mobile sinks in a WSNs and it acts as a rendezvous region for storing and retrieving collected event data. When the mobile sink crosses the network, the sensors in the rendezvous region are queried to notify the event data. The virtual infrastructure is based on honeycomb tessellation, the data dissemination is

hexagonal cell-based. A drawback in this proposal is when an event is detected and there is not a sink near the sensed area; the data aggregation and failures are not considered.

A multiple data sink node election in a multi-sink environment is presented in (Pietrabissa, 2016). This algorithm works in a distributed and iterative manner, in which the sink role is periodically reassigned to avoid the hot spot problem and increase the lifetime of the network. The network partition is according to a Centroidal Voronoid Tessellation method which leads to a spatially well-balanced distribution. This proposal does not take into account the energy depletion in the topology formation nor in the overhearing problem.

Algorithms that build a backbone connecting mobile devices in a distributed fashion using an adaptive learning scheme is presented in (Tzong, 2012). The authors consider a load balancing strategy with a zone partition in a multi-sink

WSN environment (QAZP). The movements of a node are predefined; reconfiguration to failures is not addressed.

Data Aggregation and Data Gathering (DA and DG)

In this kind of applications, the formation of the network is not important; the main goal is the way the data is collected. Some applications look for spread the data collection through defined nodes to get the Sink node, while other applications focus on the energy conservation, improving the performance, increasing the throughput, and so on. Figure 4 presents an example of Data collection in a multi-sink environment; the nodes look for the nearest sink in their area to send the information. The election of the routing nodes can be based on different parameters, defined according to the application.

Figure 3. Event detection process in the network

Figure 4. Data collection in a multi-sink environment

An example of data collection through defined nodes is presented in (Winston K. G. Seah, 2006). In this work, a virtual sink architecture for WSN that mitigates the near-sink contention by defining a group of spatially physical sink is proposed. A multi-path routing is adopted to provide alternative paths to increase the probability of successful delivery.

The authors propose a multi-tier topology by introducing local aggregation points and distributing them amongst sensing nodes and multiple local sinks. A node sends a packet simultaneously for diverse routes to multiple sinks. The network increases the probabilities to deliver the data but the energy consumption increase. The data transmission cost is high and the channel conditions are assumed without bad conditions. It is assumed that the local links are connected via high-speed links to a network where the resources are enough to support communications needs.

A data gathering for large scale sensor networks with multiple sinks (M-collectors), which

traverse several shorter sub-tours concurrently to satisfy the distance/time constraints is presented in (Ma, 2013). The objective is to find a set of data-gathering sub-tours in the network such that the number of M-collectors can be minimized.

An M-collector is responsible for gathering data from local sensors in the subarea and the information is forwarded to only one M-collector which has a connection with a final data sink. It is not guaranteed always an available sub-tour, the energy depletion during the sub-tour searching is not considered, and the transmission would be not possible if the M-collector, which has direct communication with the data sink, dies.

Classification by Technique

Clustering

In this strategy the deployed sensor nodes are organized to form clusters; every cluster has a cluster head (CH). The CH is elected according

to the node capabilities with respect to other member nodes in the cluster. CHs are able to collect data from their member nodes, processing, adding data, and forward it to one or multiples sink nodes (Figure 5).

For instance, an Energy-efficient Multi-sink Clustering Algorithm (EMCA) is proposed in (Zhanyang Xu, 2012) to solve the *energy hole* problem. Its inter-cluster and intra-cluster routing algorithm focuses on energy consumption and ensures the optimal path from nodes to its cluster head or sink. The network is divided into n equal clusters; each cluster has a cluster head chosen by considering the residual energy and sends aggregated data to the relevant sink.

The routing is used to calculate the nearest distance between the cluster head nodes and the sink nodes. The data is sent in a multi-hop manner. The energy consumption decreases while the number of the sink increases. No one reconfiguration method is considered.

In (Wang, 2015) a routing protocol algorithm that combines Ant Colony Optimization (ACO) (Dorigo, 2006), clustering, and sinks mobility techniques for home automation networks is presented. The network is divided into several clusters; each one led by a cluster head that com-

municates with a mobile sink. ACO is applicable to the guidance of the sink mobility; if the ACO fails, the mobility of the sink is being affected. Obstacles and reconfiguration are not considered, the cluster formation is energy expensive.

In (Wang et al, 2013), two algorithms for sink mobility based on clustering strategy and reduction of the energy consumption are proposed. The objective of this work is to study the influence of fixed and mobile sink strategies on home network performance in terms of energy consumption, network lifetime, and mitigation of the hot spot problem. The authors consider the study of diverse parameters including number of mobile sinks, velocity, location, and moving trajectory. Simulations are presented and compared with LEACH (Heinzelman, 2000).

Tree Formation

A tree formation strategy is a known technique to reduce the overhead and the energy consumption; it also helps to create routes to send data through the network (Figure 6). However, a bad implementation of a tree formation can create deep branches, which become an inefficient way to collect information.

Figure 5. Clustering technique

One technique for tree formation is presented in (Mottola, 2015) where distributed heuristics are embodied to minimize the number of nodes involved in routing; furthermore, there is load balancing strategy using information available in a 1-hop neighbourhood. A tree formation strategy is used to build the best available route to the sink nodes; for this purpose, multiple routes are mixed into a single one to send information to different sink nodes and to assure loaded balanced routes. The technique does not consider the density of the network nor transmission of excessive messages, depletion of energy in the routing formation, or reconfiguration.

Self-Organization

The self-organization is an effective method to prolong the lifetime of ad-hoc networks and let the nodes decide the actions to perform according to available information of the environment. The nodes have communication with their neighbour nodes and the decisions are made locally (Figure 7).

A multi-hop architecture *ICatchYou* is proposed in (Silva, 2009); it provides self-configuration abilities and allows the easy and quick integration of nodes in the network. Self-configuration

procedures are required to support the deployment of a random multi-sink.

ICatchYou performs two processes: *registration* and *updating* of information. The sink nodes should be accessible from conventional IP networks, providing the measured data in real-time for remote destinations, and allowing a simpler management and interoperability with the WSN. Depletion of the energy is not considered, and the efficiency of the nodes depends on the link quality.

In (Kiri, 2007) a system for gathering data from sensor networks with multi-sink configurations is presented; the strategy is inspired by the swarm intelligence of ants, in which each sensor node determines its next action through repeated interaction with its neighbours. Clustering and routing strategies emerge in a self-organized manner. The authors focused the problem on the communication from the sensor to the sink nodes; the number of sensors is equal to the number of clusters in the environment. Data processing and energy consumption are not considered. If a sink fails the cluster is not able to collect data. Data collection over an area may be impossible due to cluster-level power depletion where a number of events occur in a particular area.

Figure 6. Tree formation technique

A DISTRIBUTED METHOD FOR MULTI-SINK ENVIRONMENTS

In this chapter, we present an extension to a previous technique for formation and networking operation in multi-sink environments proposed in (Carlos-Mancilla, et al., 2015).

The main feature of this proposal is that the algorithm is distributed completely; nodes only use local information. The algorithm is divided into three main stages: First, the backbone formation, which is based on self-organization and clustering strategies (Figure 8). This stage allows low energy consumption, information redundancy, and robustness. In the second stage, the sink nodes initiate a tree formation procedure using a load balanced strategy. Finally, in the third stage, the nodes sense and collect the data from the environment according to the role of the node.

The main contributions of this algorithm include:

- A reliable multi-hop multi-sink algorithm, which creates tree routes from the network formation.
- Local load balancing is introduced from the tree formation.

It is assumed that a finite number of static nodes are randomly deployed in a multi-sink environment without any a-priori information. Different roles for the nodes are considered, they are: *Leader*, *Member*, *Gateway* and *Bridge*; a bridge role connects segments of the network. A segment is a set or different cluster which cannot be seen each other by a gateway node explained in more detail in (Olascuaga-Cabrera, 2011) presented in Figure 8.

The management of the nodes, reduction of the number of transmissions, delays, scheduling, and overhead control are issues addressed in the second stage. The sink nodes are the roots of the trees (level 0) and start the procedure in which the levels are assigned and distributed; also the relationship successor/predecessor is established. Redundant links and cycles are deleted, without loss of connectivity in the whole network (Figure 9).

Once the tree formation is over, the nodes change their role to Leaf node (L-node) which used to have Member and Bridge role, and Intermediate nodes (Inter-node) which used to have Leader and Gateway roles. The data collection starts in the leaf nodes until the data reach the sink node which is attached to.

FUTURE RESEARCH DIRECTIONS

Many applications can be improved using more than one technique in one application. For instance, a lot of research includes routing with tree formation technique, or cluster/tree formation strategies, event target, routing, self-organization, etc. The application of more than one method depends

on the available resources and the environment where will be applied. In (Carlos-Mancilla, 2015) a reconfiguration method for failures has to be considered and the data collection has to contemplate other possible collection strategies for unexpected event detections.

Many strategies have been proposed to improve the performance of one application considering

one or more metrics to the detriment of others. For instance, if the work is focused on routing, most of the cases the number of transmissions is excessive and the energy consumption decrease quickly, when energy consumption is the purpose of the proposal, other metrics will be sacrificed according to the number of devices, distance, channel availability, etc. In Carlos-Mancilla-2015 the proposal considers important to preserve all the mentioned metrics.

Some considerable improvements to this kind of networks are the implementation of solar panels in devices to avoid the energy constraints. Additional works look to send the information to the cloud (Internet of things- IoT) to access easily everywhere, also other researches want to add smart characteristics to the sensor for smart applications, such as home automation, health caring, special body care, and so on.

CONCLUSION

In this chapter, relevant works on distributed multi-sink wireless sensor networks (WSN) have been reviewed. It presents the evolution, design, and implementation of some important WSN techniques in the last years and the most used protocols and standards to improve the sensor applications.

One has remarked that distributed solutions are preferred over centralized ones, since distributed techniques support scalability, autonomous nodes, deployment and elimination of nodes; also, it is possible to use self-organization strategies inspired from nature, in which the interaction is made only with neighbour nodes.

As an example of distributed strategy for multi sink network formation, the last section over-viewed a proposal that involves a self-organization strategy for backbone formation; afterward, the tree formation strategy uses local information and builds the load balanced trees over the formed

network in a multi-sink environment. Finally, sensing and data collection processes are executed at every defined period of time. The presented algorithm copes with challenging problems inherent to wireless sensors, such as energy consumption, memory, latency, loss of messages, routing, and the number of retransmissions that affect the performance of the whole network.

KEY TERMS AND DEFINITIONS

Ad-Hoc Networks: The network topology is determined by the sensor locations, which are not known a priori, and do not require a router or a controlled wireless base station. The data collection is dynamically defined with the connectivity of the nodes.

Distributed Strategies: They are schemes in which the task coordination is not performed by a single sensor or sink; instead, the devices interact among them to achieve a common goal through message passing.

Multi-Sink Environments: It is a networking problem in which two or more base nodes or sinks are deployed in an environment to collect data; multiple sinks allow the distribution of traffic with the aim of reducing congestions.

Self-Organisation: The coordination and control needed to form a network emerge through the local interaction of a group of sensors/devices from an initially disordered network y/o system.

Sensor Networks: They are formed by a group of tiny, typically battery-powered devices and wireless infrastructure that sense, observe and record conditions in diverse environments.

Wireless Sensors: They are autonomous devices provided with sensing communication capabilities and limited memory and power resources.

A Graph–Intersection–Based Algorithm to Determine Maximum Lifetime Communication Topologies for Cognitive Radio Ad Hoc Networks

Natarajan Meghanathan
Jackson State University, USA

INTRODUCTION

A cognitive radio is a software-defined radio that can dynamically adapt its transmission parameters to the channels (frequencies) available for use in the operating environment (Akyildiz et. al., 2006). A cognitive radio network (CRN) is thus a network of wireless devices embedded with cognitive radios that can sense the available channels in the neighborhood and switch the communication channel, if needed. Cognitive radios have been considered as a promising solution to alleviate the spectrum scarcity problem (Zhao & Sadler, 2007). Accordingly, CRNs typically comprise of two categories of users: primary users (PUs) who own licensed channels and secondary users (SUs) who do not own any licensed channel (Akyildiz et. al., 2006). The SUs use the licensed channels of the PUs when the latter do not use them. When the PUs of the currently used channels become active, an SU relinquishes the channel and switches to any other available PU channel.

In this chapter, we target a well-known category of CRNs called the cognitive radio ad hoc networks (CRAHNs) - a self-organized ad hoc network of the licensed PU nodes and the unlicensed SU nodes (Akyildiz et. al., 2009). Depending on the activity status of the PU nodes, the set of common PU channels in the neighborhood of the SU nodes changes dynamically with time. Thus, even in a static network of SU nodes and PU nodes, communication topologies (like paths and trees) that connect the SU nodes may have to be frequently

reconfigured depending on the availability of the PU channels in the SU-SU neighborhoods. Not much work has been done on determining stable paths or trees that could exist for a longer time in a CRAHN. Specifically, to the best of our knowledge, there has been no work done to determine stable sequence of a communication topology that spans (i.e., connect all the SU nodes) the entire CRAHN network of SU nodes.

Our focus in this chapter is to develop a generic benchmarking algorithm that can be used to arrive at upper bounds for the lifetime of any communication topology that spans the entire network of SU nodes. Referred to as the Maximum Lifetime Communication Topology (MLCT) algorithm, the algorithm can be used to determine a stable sequence of instances of any communication topology that spans the entire network of SU nodes (say, shortest path tree, minimum spanning tree, connected dominating set, etc) for the lifetime of the network as long as there is a polynomial-time algorithm or heuristic to determine that topology.

BACKGROUND

Most of the work done so far in the CRAHN literature focused on developing routing solutions that are either full spectrum knowledge based or local spectrum knowledge based. The full spectrum knowledge based solutions assume each SU node to be completely aware of all the available PU channels in the network and choose optimal

routes with respect to either minimum number of hops per SU-SU path (Xin et al., 2005), maximum conflict-free assignment (Zhou et al., 2009) of PU channels or minimum number of channel switches per SU-SU path (Xin et al., 2008); there is bound to be switching of channels when none of the common available PU channels for the end nodes of an SU-SU link are the same as the preferred PU channels for one or both the end nodes to which they stay tuned by default for transmission and reception. Such full spectrum knowledge-based solutions take a centralized approach like we took in this chapter; however, the full spectrum knowledge for the current time instant alone cannot be used to arrive at benchmarks for the routing metric, if one intends to stay with a route as long as it exists.

The local spectrum knowledge based routing solutions are distributed in nature and rely only on the spectrum information gathered in the neighborhood through the common control channel (Lo, 2011). The local spectrum knowledge based routing solutions proposed so far could be classified into sub classes that target at optimizing a particular metric in a distributed fashion. The minimum power routing protocol (Pyo & Hasegawa, 2007) is designed to discover SU-SU paths that incur lower energy consumption by taking into consideration the energy loss incurred due to transmission, reception, broadcast route discovery as well as channel switching. The bandwidth footprint (BFP) minimization-based routing protocol (Shi & Hou, 2008) attempts at discovering an s - d (source-destination) path that will minimally impact the on-going s - d sessions with respect to the interference area of the SU nodes (called the bandwidth footprint). Xie et al (2010) evaluated the tradeoffs associated with farthest neighbor routing (FNR) and nearest neighbor routing (NNR) for CRAHNs; results indicate FNR to achieve better end-to-end channel utilization and reliability and NNR to be relatively more energy-efficient. Cheng et al (2007a), Cheng et al (2007b) and Ma et al (2008) attempted to develop delay-sensitive routing protocols for CRAHNs: while

Cheng et al (2007a) and Cheng et al (2007b) focus on minimizing the sum of the channel switching and access delays at the intermediate nodes, Ma et al (2008) focus on minimizing the sum of the queuing delays at the intermediate nodes.

In earlier works, we had proposed separate benchmarking algorithms based on the idea of taking graph intersections (Meghanathan, 2008) to determine stable sequence of unicast paths, multicast Steiner trees and broadcast connected dominating sets for mobile ad hoc networks (MANETs) and to determine stable sequence of data gathering trees (Meghanathan & Mumford, 2013) for wireless mobile sensor networks (WMSNs). The characteristic of both MANETs and WMSNs is that the nodes are mobile and it is the mobility of the nodes that triggers the topology changes. On the other hand, nodes in the CRAHNs considered in this research are static and it is the availability of the PU channels that changes dynamically with time, triggering changes in the communication topology of interest.

NETWORK MODEL AND ASSUMPTIONS

We assume a centralized setup of the CRAHN comprising of the licensed primary users (PU nodes) and unlicensed secondary users (SU nodes) uniform-randomly distributed. Each PU node is assumed to own a licensed channel that has a unique frequency and is identified with the ID of the PU node itself. Both the PU nodes and SU nodes are assumed to be static. Let R be the fixed transmission range for both the categories of nodes. A PU node is said to be a neighbor of an SU node if the Euclidean distance between the two nodes is less than or equal to R . Accordingly, we say that a PU channel is available for use by an SU node at a particular time instant only if the corresponding PU node is in the neighborhood of the SU node (which is always the case, as the nodes are static) and that the PU node is idle (i.e., the PU node is turned OFF) and not using its licensed

channel at that time instant. We assume a PU channel is turned ON and OFF alternatively for a random time period uniform-randomly chosen each time from the range $[0 \dots MAX_{Random_ON}]$ and $[0 \dots MAX_{Random_OFF}]$ respectively.

We model a time-invariant SU graph $G_t(SU)$ of the CRAHN as the graph comprising of only the SU nodes; a link exists between two SU nodes u and v in $G_t(SU)$ if and only if the Euclidean distance between the two SU nodes is within the transmission range, R . We sample the network periodically for every t_{sample} seconds. We model a time-variant static SU graph $G_t(SU)$ of the CRAHN as a snapshot graph of the CRAHN at time instant t : the graph comprises of both the SU nodes and PU nodes; there is no link between any two PU nodes or between a PU node and an SU node; there exists a link between two SU nodes u and v in $G_t(SU)$ if and only if there exists a link between u and v in $G_t(SU)$ as well as there exists at least one common PU node whose licensed channel is available in the neighborhood of both u and v for use (i.e., the PU node is turned OFF). We model a time-variant mobile SU graph $G_{t \dots t+k}(SU) = G_t(SU) \cap G_{t+1}(SU) \cap \dots \cap G_{t+k}(SU)$ such that $G_{t \dots t+k}(SU)$ is connected (i.e., spans all the SU nodes), wherein $G_t(SU)$, $G_{t+1}(SU)$, $G_{t+2}(SU)$, ..., $G_{t+k}(SU)$ are respectively the static SU graphs at time instants sampled at time instants t , $t+1$, $t+2$, ..., and $t+k$.

GENERIC ALGORITHM TO DETERMINE MAXIMUM LIFETIME COMMUNICATION TOPOLOGY

Given the knowledge of the future availability of the PU channels, the MLCT algorithm (pseudo code in Figure 1) works as follows: At a time instant t for which we want to determine a stable communication topology that spans the entire network of SU nodes (say a shortest path tree rooted at source SU node s), we check if the static SU graph $G_t(SU)$ is connected (i.e., there exists a

path between any two SU nodes). We can check the connectivity of an SU graph (static graph or mobile graph) using the Breadth First Search (BFS) algorithm (Cormen et al., 2009). If all the vertices of the graph can be visited by running BFS from any arbitrarily chosen node, then the graph is connected; otherwise, not. If $G_t(SU)$ is connected, the network-wide communication topology of interest exists at time instant t . We then proceed to the next sampling time instant $t+1$ and take the intersection of the graphs $G_t(SU)$ and $G_{t+1}(SU)$ and refer to the intersection graph as the mobile graph $G_{t \dots t+1}(SU) = G_t(SU) \cap G_{t+1}(SU)$. If $G_{t \dots t+1}(SU)$ is connected, we continue to proceed to the next sampling time instant $t+2$ and check whether $G_{t \dots t+2}(SU) = G_t(SU) \cap G_{t+1}(SU) \cap G_{t+2}(SU)$ is connected. We continue like this until we come across sampling time instants $t+k$ and $t+k+1$ such that $G_{t \dots t+k}(SU)$ is connected and $G_{t \dots t+k+1}(SU)$ is not connected. If $G_{t \dots t+k}(SU)$ is connected, it implies the communication topology of interest (say a shortest path tree rooted at source node s) exists in each of the static graph snapshots $G_t(SU)$, $G_{t+1}(SU)$, ..., $G_{t+k}(SU)$. We could use that communication topology across all of these time instants t , $t+1$, ..., $t+k$. We repeat the above procedure starting from time instant $t+k+1$ to find the next stable mobile graph and communication topology of the sequence and continue likewise until the end of the network session.

The MLCT algorithm finds for us a stable sequence of instances of the mobile graph and the communication topology of interest (say the shortest path tree) such that the number of transitions from one instance of the topology to another in the sequence is the global minimum. The average lifetime of the mobile graphs in the stable sequence found by the MLCT algorithm would serve as an upper bound (benchmark) for any network-wide communication topology (be it a shortest path tree, spanning tree, connected dominating set, etc) that spans all the SU nodes found by any centralized or distributed algorithm for CRAHNs.

Figure 1. Pseudo code of the maximum lifetime communication topology algorithm and its application to determine stable sequence of maximum lifetime shortest path trees (MLSPTs)

Input: Static graphs $G_t(\text{SU})$ for all the sampling time instants $t \in 1 \dots T$ of the network session
Source node s
Output: Stable sequence of mobile graphs and maximum lifetime shortest path trees (MLSPTs)
Auxiliary variables: i, j
Initialization: $i = 1, j = 1, \text{MLSPT}_{1 \dots T}(\text{SU}) = \phi; \text{Stable_G}_{1 \dots T}(\text{SU}) = \phi$
Begin MLCT Algorithm
1 **while** ($i \leq T$) **do**
2 Find a mobile graph $G_{i,j}(\text{SU}) = G_i(\text{SU}) \cap G_{i+1}(\text{SU}) \cap \dots \cap G_j(\text{SU})$ such that
 $G_{i,j}(\text{SU})$ is connected and $G_{i,j+1}(\text{SU})$ is not connected.
3 $\text{Stable_G}_{1 \dots T}(\text{SU}) = \text{Stable_G}_{1 \dots T}(\text{SU}) \cup \{G_{i,j}(\text{SU})\}$
4 Find a shortest path tree $\text{SPT}_{i,j}(\text{SU}) = \text{BFS}(G_{i,j}(\text{SU}), s)$
5 $\text{MLSPT}_{1 \dots T}(\text{SU}) = \text{MLSPT}_{1 \dots T}(\text{SU}) \cup \{\text{SPT}_{i,j}(\text{SU})\}$
6 $i = j+1$
7 **end while**
8 **return** $\text{MLSPT}_{1 \dots T}(\text{SU})$ and $\text{Stable_G}_{1 \dots T}(\text{SU})$
End MLCT Algorithm

Time Complexity of the MLCT Algorithm

The time complexity of the MLCT algorithm depends on the time complexity to determine the mobile graphs and the number of times we run the BFS algorithm to determine the connectivity of the static graphs and mobile graphs as well as on the time complexity of the algorithm used to determine the underlying communication topology of interest. In general, if $\Theta(X)$ is the run-time complexity to determine the communication topology of interest on a particular SU graph, the overall-time complexity to run the MLCT algorithm to determine a stable sequence of the communication topology of interest would be: $\Theta(T*(V+E+X))$, where $\Theta(V+E)$ is the time complexity of the BFS algorithm and T is the number of instances on which we have to either run the BFS algorithm to check for connectivity of the mobile graphs or run the underlying algorithm of complexity $\Theta(X)$ for the communication topology of interest or both.

Example to Illustrate the Execution of the MLCT Algorithm

Figure 2 illustrates an informative example for the execution of the MLCT algorithm to determine a stable sequence of shortest path trees (node 1 as the source node) across five time instants 1, 2, ..., 5. The SU nodes (with white background) are numbered, while the PU nodes (blue or red-colored) are not numbered. In the static graphs at time instants 1, 2, ..., 5, an active PU node (i.e., is turned ON) is shown as a red-colored node and an idle PU node (i.e., is turned OFF) is shown as a blue-colored node. The dotted links represent the presence of a PU node in the neighborhood of the SU node(s). The time-invariant initial graph of SU nodes represents the network of SU nodes with all possible links: there exists a link between any two SU nodes in this graph if the two SU nodes are within the transmission range of each other. In the time-variant static SU graphs for time instants 1, 2, ..., 5, there exists a link between any two SU nodes if and only if there exists a

Figure 2. Example to illustrate the execution of the maximum lifetime communication topology algorithm for shortest path trees in a cognitive radio ad hoc network of SU and PU nodes

link between the two nodes in the time-invariant SU graph as well as there exists an available/ idle PU node in the neighborhood of the two SU nodes at that time instant. The minimum-hop/ minimum-height shortest path trees (MHSPTs)

incur four transitions (tree changes) with a time-averaged height of $(3+3+3+4+4)/5 = 3.4$. The MLCT-MLSPTs incur only one tree transition (at time instant 4), with a time-averaged height of $(4+4+4+5+5)/5 = 4.4$.

Proof of Correctness of the MLCT Algorithm

We now prove that the MLCT algorithm does determine a stable sequence of the mobile graphs and the corresponding instances of the communication topology of interest such that the number of transitions from one instance of the topology to another in the sequence is the global minimum (i.e., optimum). We use the approach of proof by contradiction. Let m be the number of transitions (change from one instance to another) in the sequence of instances of the communication topology determined by the MLCT algorithm. Let there be a hypothetical algorithm that determines a sequence of instances of the communication topology such that the number of transitions is m' wherein $m' < m$. If such a hypothetical algorithm exists, for m to be greater than m' , (without loss of generality) there should be a mobile graph $G_{t+p...t+s}$ (SU) for which the MLCT algorithm should have incurred at least one transition in the time span from $t+p$ to $t+s$, where t is the beginning time instant of the network session and $p < s$ are the increments to t indicating sampling time instants $t+p$ and $t+s$ respectively, but that the hypothetical algorithm did not incur any transition in the communication topology from $t+p$ to $t+s$. If the hypothetical algorithm were to find a network-wide communication topology that exists from time instants $t+p$ to $t+s$, the mobile graph $G_{t+p...t+s}$ (SU) must be connected. But, the MLCT algorithm underwent at least one transition during the time period $t+p$ to $t+s$ because the mobile graph $G_{t+p...t+s}$ (SU) was not connected. This implies the hypothetical algorithm cannot find an instance of the mobile graph and the communication topology of interest whose duration of existence is larger than that determined by the MLCT algorithm. Hence, the sequence of instances of the communication topology determined by the hypothetical algorithm should have undergone at least the same number of transitions as the sequence of instances of the communication topology determined by the MLCT algorithm, which means $m' \geq m$. This is a

contradiction to the initial hypothesis that $m' < m$ and hence the hypothesis cannot be true.

N

SIMULATIONS

We developed a discrete-event simulator in Java for Cognitive Radio Ad hoc Networks (CRAHNs) and implemented the Maximum Lifetime Communication Topology (MLCT) algorithm and adapted it to determine a sequence of maximum lifetime shortest path trees (MLSPTs) among the SU nodes. We also implemented the algorithm to determine a sequence of minimum hop shortest path trees (MHSPTs) that determines a MHSPT on a particular static SU graph and uses it in the static SU graphs for the subsequent time instants as long as the MHSPT exists. We sample the network topology for every 0.25 seconds. The total simulation time is 1000 seconds. The source node for a particular MHSPT or MLSPT is chosen randomly from the set of SU nodes. The network dimensions are 1000m x 1000m. The number of SU nodes is fixed at 50; the number of PU nodes is varied from 25 to 100 nodes. The transmission range of both the SU nodes and PU nodes is fixed to be 250m. The values of the parameters MAX_{Random_ON} and MAX_{Random_OFF} are each: 5, 10 and 20 seconds. The simulation results presented in Figure 3 and Figure 4 are averaged over 20 runs for each combination of values for PU-SU ratio, MAX_{Random_ON} and MAX_{Random_OFF} .

The MLSPTs incur significantly larger values of tree lifetime compared to the MHSPTs for all the scenarios (Figure 3). The percentage values shown in Figure 3 are based on the ratio of the lifetime of the MLSPTs to that of the MHSPTs, indicating the percentage difference in the lifetimes of the two trees. For a fixed value of the MAX_{Random_ON} and MAX_{Random_OFF} parameters, the rate at which the average lifetime of the MLSPTs increases is significantly faster than the rate at which the average lifetime of the MHSPTs increases. The MLCT algorithm makes use of the knowledge about the availability of the PU channels in future and is able

Figure 3. Lifetime of maximum lifetime shortest path trees and minimum hop shortest path trees

to find a long-living shortest path tree that exists in several of the static SU graphs spanning a mobile graph; on the other hand, the MHSPT algorithm could make use of only information about the availability of the PU channels in the particular SU graph at which it is run. The increase in the average lifetime of the MLSPTs (with increase in the PU-SU ratio) gets enhanced with increase in the availability time of the PU channels (i.e., with increase in the value of MAX_{Random_OFF}) and with increase in the number of PU channels. When the PU channels are used by their PU nodes for a longer time and remain unavailable for the SU nodes, the rate of increase for the average lifetime of the MLSPTs reduces.

The average tree height (Figure 4) is the time-averaged height of the shortest path trees determined for the sequence of MLSPTs and MHSPTs. The tree height is a measure of the diameter of the network (the maximum of the minimum hop count of the paths between any two nodes). We observe the MLSPTs to incur at most 12% larger height than MHSPTs. There is no definite trend in the difference in the height between the two trees across the simulation conditions. With the significant gains in the lifetime of the MLSPTs

and an inconsequential increase in the height of the trees, we could infer that there is no stability-hop count tradeoff in CRAHNS.

FUTURE RESEARCH DIRECTIONS

In future, we plan to develop a distributed version of the MLCT algorithm to determine a stable sequence of network-wide communication topologies (such as shortest path trees) based on the predicted link-lifetime information (Guan et al., 2010; Li et al., 2013) of a CRAHN. We could then compare the relative performance of the distributed vs. centralized versions of the MLCT algorithms and analyze the stability-hop count tradeoff in constrained real-time settings. Besides, we plan to apply the proposed MLCT algorithm on a CRAHN of mobile SU nodes and study the impact of topology changes due to the fluctuations in the availability of the PU channels as well as due to the mobility of the SU nodes. In addition, we plan to extend the stability-hop count tradeoff studies to simulations involving energy-constrained SU nodes so that any potential tradeoff involving node lifetime (time of first node failure

Figure 4. Height of maximum lifetime shortest path trees and minimum hop shortest path trees

due to energy exhaustion) and/or network lifetime (time of network disconnection due to the failure of one or more nodes due to energy exhaustion) could be analyzed.

CONCLUSION

The high-level contribution of this chapter is the proposal of a centralized benchmarking algorithm to determine stable sequence of mobile graphs and the corresponding instances of a communication topology that spans all the secondary user (SU) nodes in a cognitive radio ad hoc network (CRAHN) environment. Referred to as the Maximum Lifetime Communication Topology (MLCT) algorithm, the algorithm is generic in nature and can be applied to determine a stable sequence of any communication topology of interest as long as there is an algorithm or heuristic to determine the topology. The MLCT algorithm uses a greedy strategy of determining a mobile graph that spans for the largest number of time instants starting from the current time instant and running an appropriate algorithm for the communication topology of interest on the mobile graph. We have shown that such a greedy strategy does indeed gives an optimal solution (benchmark) for the minimum number of transitions (and hence a maximum lifetime) among the instances of the communication topology determined for the duration of the network session.

KEY TERMS AND DEFINITIONS

Ad hoc Network: A decentralized and self-organized network of wireless nodes without any a priori dependence on any infrastructure.

Algorithm: A sequence of steps to perform a particular task.

Cognitive Radio: A software-defined radio that can dynamically adapt its transmission parameters to the channels (frequencies) available for use in the operating environment.

Communication Topology: An arrangement of the nodes in the network that can be used for communication between any two nodes in the network.

Mobile Graph: A sequence of static graphs generated for a time period.

Primary User (PU): Licensed user of a cognitive radio network.

Secondary User (SU): Unlicensed user of a cognitive radio network who uses one or more available channels of a PU.

Shortest Path Tree: A communication topology that is rooted at a specific node and connects every other node in the network on the shortest path (minimum number of hops) to the root node.

Static Graph: Snapshot of a network of PUs and SUs at any particular time instant.

Topology Lifetime: The duration of existence of a communication topology.

Improving Quality of Business in Next Generation Telecom Networks

Vesna Radonjić Đogatović
University of Belgrade, Serbia

INTRODUCTION

Business processes in telecommunication sector have evolved from rigid structures to a highly competitive environment due to the dynamics of the open market. Future telecommunications infrastructure are expected to be built upon the concept of next generation network (NGN) referring to an architecture of telecommunication core and access networks, which assumes transport of all information and services over a common network, typically built around the Internet Protocol (IP).

Many service providers (SPs) are looking to NGN services as a means to attract and/or retain the most gainful users. In NGN users are expected to choose the SP offering the best price and quality of service (QoS) combination. As a result, SPs operating in the same telecommunication market will end up competing for users by adjusting QoS they offer and the price they charge for their services.

Quality of NGN services can be estimated based on the three aspects: QoS, quality of experience (QoE) and quality of business (QoBiz). The main goal for SP is to maximize his revenue while providing users the required QoS at the acceptable price. QoS can be defined as a set of characteristics of a telecommunications service that bear on its ability to satisfy users' requirements (ITU-T E.800, 2008). While QoS is related to the service performances that can be measured and controlled, QoE relates to the experience realized by a user when using the service and it depends upon users' actions and subjective opinions. In addition to SPs' aspirations to ensure the required QoS to their users, profitability is of the most impor-

tance to them. QoBiz in particular covers service providers' profitability. It deals with the financial aspects of service provisioning and refers to all those parameters that are expressed in monetary units. QoS, QoE and QoBiz are integral parts of a service level agreement (SLA) which can be contracted between two SPs or a SP and a user.

This chapter aims to provide new possibilities for SPs to enhance their revenues using the appropriate pricing scheme. Features and applicability of responsive pricing scheme for charging end users in NGN are discussed. Game theory is used as an underlying concept for the implementation of pricing.

BACKGROUND

Pricing with QoS guarantees has gained a strong momentum in telecommunication networks in past decade. It has led to a new interdisciplinary research area of "Telecommunication Economics", which investigates telecommunication networks from an economical rather than from a technical perspective and allows innovative solutions in network management, control and pricing (Courcoubetis & Weber, 2003).

QoS describes the ability of a network to provide a service with an assured service level but it appears that in NGN QoS differentiation will not provide a suitable economic framework for the trade-off between quality delivered by SPs and willingness to pay from users' side. QoE is an alternative framework for pricing service quality according to the user perception (ITU-T G.1011, 2013). It is affected not only by technical (i.e. QoS)

aspects, but on non-technical aspects of service too, such as service set-up, content, price and customer support, which are essential for both QoE and QoBiz evaluation. The distinction between QoS, QoE and QoBiz metrics in case of Internet services are first emphasized by Moorsel (2001). In Wolter and Moorsel (2001) possible relationships between QoS and QoBiz metrics are pointed out, particularly the effects of QoS degradations on the profitability of e-services. This research considers dynamic relationship between QoS and QoBiz metrics with pricing as an important tool for balancing users' behaviour. Further, for the purpose of evaluating the impact of service composition and utility computing on QoBiz aspects of SPs, a distributed architecture of control systems that manages SLAs is proposed in Machiraju et al. (2002). Yu and Bouguettaya (2007) proposed the model for supporting optimized access of web services through service-oriented queries. Besides QoBiz parameters, this model captures functionality and users' behaviour, as the key features of web services. Bjekovic and Kubicki (2011) address the need for an integration of non-functional aspects of service from the business perspective with aim of improving cooperation among business enterprises. In Radonjic Djogatovic et al. (2013) the model performing transparent mapping from QoS to QoBiz parameters is proposed. This QoBiz model is based on several QoS parameters that significantly affect both users' demand and a SP's requirements from the business perspective.

Telecom provider's QoBiz is tightly related to the selection of the appropriate network pricing method. Price based bandwidth allocation has been the focus of many research efforts that aimed to guarantee an appropriate QoS to users. Some methods allow congestion which results in blocking of the lower-priced traffic classes and the acceptance of the higher-priced traffic classes in case of congestion (Marbach, 2004). The concept of responsive pricing was proposed with the aim to incorporate a feedback generated by the network. When the network announces a price based on the cost of using network resources

price-sensitive users adjust their traffic in accordance of their own network service valuation (MacKie-Mason, Murphy, L. & Murphy, J., 1997). Chod and Rudi (2005) considered responsive pricing with resource flexibility as well as effects of demands variability and correlation, assuming normally distributed demand curve. In Ninan and Devetsikiotis (2005) a model for incorporating pricing in NGNs with users sharing bandwidth under a fixed charge per bandwidth amount was presented. Optimal resource allocation of NGN services under a flat pricing scheme and QoS policies were considered by Kallitsis et al. (2007). Congestion pricing with various user demands over time was analyzed by Hande et al. (2010). With the goal of maximization SPs' revenue the same authors applied the optimal combination of flat-rate and usage-based access price components. The importance of selection of the appropriate pricing method for a business model framework in case of providing assured quality services is emphasized in Ghezzi et al. (2014). An overview of usage-based pricing schemes and accounting protocols that can be used in NGN are given in Radonjic Djogatovic and Kostic-Ljubisavljevic (2015).

PRICING AND QUALITY ISSUES IN NGN

The evolution of networks to NGNs must allow the continuity of, and interoperability with, existing networks while enabling the implementation of new capabilities (ITU-T Y.2012, 2010). Suitable pricing and business models need to be designed which is expected to provide the appropriate incentives for both SPs and users.

Generally, the concept of pricing implies the process of determining prices which should be based on the appropriate pricing model and controlled by a pricing policy. It is expected that competition will force SPs to rapidly create and deploy different pricing concepts with aim of fulfilment a trade-off between providing satisfying

user's utility and provider's profit, still preserving implementation efficiency and feasibility. User's utility can be expressed as a function of available network resource offered to a user which indicates a user's sensitivity to changes in QoS. A wide range of different pricing schemes is likely to be applied in NGN (Ninan & Devetsikiotis, 2005; Pandey, Ghosal & Mukherjee, 2007; Radonjic & Acimovic-Raspopovic, 2010). Pricing schemes that should be implemented in NGN have to be defined and evaluated with respect to the heterogeneous technical, economic and social aspects. The main evaluation criteria encompass efficiency in the context of maximizing utilities of users and providers, fairness and feasibility.

In NGN there is a need for shifting from static pricing schemes, in which users are charged independently of the resource consumption and QoS delivered, towards dynamic pricing schemes. In dynamic pricing, price is determined as a cost per unit of consumption and according to the level of QoS guarantees provided for the observed service class. The main problem with dynamic pricing refers to the need of intensive monitoring of network resources in order to dynamically adjust per-class prices to resources usage and the QoS provided for each service class. Any NGN architecture must guarantee fair access to the shared resources in the access network and control load distribution with aim of avoiding focused overload in the core. Also, NGN should support hard guarantees to users and pricing different QoS classes.

Due to the rapidly increasing deployment of interactive and multimedia applications in telecommunication services, QoS becomes an integral part of various protocols and mechanisms for enabling computing and telecommunication systems. QoS is defined by SLA which consists of two parts: the technical part and the administrative part. The technical part encompasses a set of descriptors and associated attributes that describe the particular service class and the traffic profile. The administrative part covers financial and legal aspects: information about pricing, charging, billing and payment, penalties for both user and

service provider in the case of contract violation, etc. (Stojanovic, Kostic-Ljubisavljevic & Radonjic Djogatovic, 2013). As users' needs are constantly increasing, as well as competition between service providers, SLA becomes more complex.

Although QoS is usually represented by delay, loss and jitter, which are difficult to measure precisely, frequently used QoS parameters for determination whether a required service level is being achieved, are network availability and bandwidth. Network availability includes the availability of many items the network consists of, e.g. multiple physical connections, networking device redundancy. It is also important to distinguish available and guaranteed bandwidth. In many dynamic pricing schemes users are allowed to compete for the available bandwidth and their obtained bandwidth depends upon amount of traffic from other users in the network at any observed time (Chod & Rudi, 2005). The term guaranteed bandwidth implies a guaranteed minimum bandwidth SP provides or burst bandwidth in SLA. The service with guaranteed bandwidth has higher priority and is priced higher compared to the available bandwidth service.

By introducing QoS differentiation users are encouraged to choose the service that meets their needs in the most adequate manner, which can be achieved through pricing. Providing service with strong QoS guarantees keeps users satisfied and thereby maintains the confidence in the SP. However, it is necessary to take into account user experience and business indicators too. Therefore, quality of NGN services can be estimated based on three aspects: QoS, QoE and QoBiz.

Obviously, QoS is related to the service performances that can be measured and controlled, while QoE relates to the experience realized by a user when using the service. QoE depends upon users' actions and subjective opinions. It takes into consideration users' satisfaction with the service, subjective evaluation, the degree of their expectations fulfilment and in what context they use it or intend to (Barakovic, S., Barakovic, J. & Bajric, 2010).

In addition to SPs' aspirations to ensure the required QoS to their users, QoBiz is an important aspect in providing quality of NGN services that is being increasingly used in the pursuit of better business. It deals with the financial aspect of service provisioning and refers specifically to measures such as service price, service provisioning costs, revenue from the service provisioning, revenue per transaction, lost transactions etc. In general, QoBiz parameters are all those parameters that are expressed in monetary units. According to the more precise interpretation, it is a monetary value that matches the quality of delivered service, expressed through connection of QoS parameters with monetary value within the SLA (Radonjic Djogatovic, Kostic-Ljubisavljevic & Stojanovic, 2013).

A MODEL FOR QUALITY OF BUSINESS IMPROVEMENT

A model for QoBiz improvement of next generation telecom network should include business aspects that are specific and important for telecom sector. It should reflect involved parties' preferences which allow discovering, negotiating and contracting a service between a user and a provider.

This chapter proposes an approach for eliminating or at least alleviating congestion along with service price optimization regarding QoS and QoE and revenue maximization, which is reflected on QoBiz. It has been done via proper bandwidth assignment considering the capacity constraint, i.e. adapting the network price to optimize network performances. It is achieved by a usage-based scheme with users getting charged for the amount of traffic they consume. For maintaining social optimality these charges would have to be set equal to the marginal cost of usage. Since bandwidth scarcity occurs only during congestion, this marginal cost is essentially the same as the congestion cost.

In order to achieve satisfying network and economic efficiency the responsive pricing scheme is

used (Chod & Rudi, 2005). Price is emphasized as an alternative means for congestion control to ensure proper network operation and in particular to guarantee different service levels. In this pricing scheme, in the case of high network utilization, provider increases the prices for the resources and adaptive users then reduce traffic offered to the network. Similarly, in the case of low network utilization, by decreasing the price adaptive users are encouraged to increase their offered traffic.

In the proposed model bandwidth management server (BMS) is introduced in order to enhance scalability and to allow connection control functions independently of the underlying network, which makes it suitable for NGN. BMS acts as an interface between the connection control functions and the network specific bearer functions. The interface between BMS and the underlying network elements is provided to allow BMS to set up and tear down aggregate bandwidth reservations across the network. The most important features of BMS are the ability to release bandwidth when it is no longer needed and to reserve bandwidth to the particular destination of the particular QoS class. The underlying network elements must be able to inform BMS of any changes affecting current reservations. The interface should allow this information to be passed upwards to BMS immediately such an event takes place and the information should reach BMS with the shortest possible delay.

During SLA negotiation, the SP estimates resource usage according to the required traffic profile. Although it is common that the agreement between the SP and a user for a service consumption has to be settled for a long time period, in this model allocations are performed in short time scales. In practice, it would be impossible for each user to update his bandwidth in a short time scale. Instead of that, with the aim of maximizing SP's revenue, updates are performed by BMS considering network congestion and network capacity utilization. Updates are based on users' parameters of desired bandwidth, maximal price they are willing to pay and their individual utility

functions. During the service provisioning interval, the usage-based traffic monitoring should be applied only with respect to deviations from the contracted traffic profile. Such approach is called hybrid pricing scheme. It needs less storage of monitoring data in comparison with monitoring per unit of consumption (i.e. dynamic pricing) and should be implemented only at the edge routers, in which traffic conditioning is performed. The solution of the problem encompasses the optimal bandwidth allocation and the optimal price for that allocation. The actual price is calculated at the end of service provisioning interval according to SP's specific policy, which should aim to force users to wisely select the most appropriate traffic profiles and to properly adjust to them. Each user has to pay the price that is equal to the sum of products of each optimal price and his bandwidth consumption during all his sessions in the agreed time period.

In the proposed model, problem of determining service prices is divided into optimization with respect to users' utility and the optimization of the provider's revenue. In this fashion, the model incorporates not only QoS but QoE and QoBiz too. Users' preferences may be modelled with utility functions that describe users' sensitivity to changes of QoS. Since it is not easy to predict actual QoS parameters, such as delay or packet losses in most real networks, utility is often expressed as a function of the amount of available network resources (i.e. bandwidth) offered to each user (Ninan & Devetsikiotis, 2005). Thus, the utility indirectly indicates user's sensitivity to changes in QoS.

The optimization procedure is performed for different categories of users, which can be alternatively done for different service classes. According to the elasticity criteria, users are classified into three categories: inelastic, partially elastic and elastic users (Radonjic Djogatovic & Kostic-Ljubisavljevic, 2015). Inelastic users are users who have strict requirements in terms of delay but can tolerate losses to some extent and their utility has been most commonly described

by the sigmoid function. A utility function which best models elastic and partially elastic users' behaviour is a generalization of the logarithmic function. Elastic users do not tolerate losses but can accept a delay to some extent. Partially elastic users are also not tolerant of losses but they have stronger requirements in respect to delay. Users' utility functions vary in accordance to the elasticity criterion of a user. For all users' types, QoS is defined by bandwidth, θ obtained from the SP. Users are assumed to be non-cooperative, meaning that they refuse to reveal their utility functions to one another in the fear of being misused.

The SP employs a usage-based pricing policy by charging M per unit bandwidth consumed. Depending upon the QoS requested, i.e. the class of service he chose, each user would require a minimum bandwidth γ . Fewer bandwidth than γ on average is of no utility to the user (Ninan & Devetsikiotis, 2005). The law of diminishing marginal utility ensures that the user derives the same amount of satisfaction from any bandwidth more than the maximum π . It is considered that the user is willing to pay a maximum price m per unit of bandwidth. When the price M equals the maximal price m , the user will desire only the minimum acceptable bandwidth, γ . For all types of users, any price beyond the maximal price reduces a user's desired bandwidth to zero. Each user will try to choose his bandwidth θ so as to maximize his net benefit (i.e., utility minus cost). Ideally any resource allocation between users should ensure that the total user utility is maximized. On the other hand, the SP's utility T depends on the total revenue generated and hence is a function of the market price and the bandwidth allocated to the various users. In order to maximize his revenue, the SP settles the price per bandwidth unit according to the concept of responsive pricing reflecting the state of resource utilization.

The interaction of the SP and users is defined as a Stackelberg leader-follower game within responsive pricing scheme driving the system towards optimality. Generally, in Stackelberg model at least one player is defined as the leader who

can make the decision and commit the strategy before other players who are defined as followers (Briest, Hoefer & Krysta, 2008). In the proposed model, players are the SP, acting as the leader and users, acting as followers. They act in a definite sequence and interaction between them is dynamic rather than static. The strategy chosen by the SP can be observed by users, so they can adapt their decisions in accordance to their preferences. The SP can choose such a strategy which allows him to maximize revenues, assuming that users will choose their best responses. With backward induction, the best responses of users are obtained first. The best responses of both SP and users in this leader-follower competition can be obtained in the following way. Given the price offered by the SP, based on a demand function, the amount of bandwidth users requested can be determined. For example, if the price is high, the amount of bandwidth requested by users will be small and vice versa. Then, this best response is used to compute the revenue of the SP, and he chooses a strategy that leads to his revenue maximization.

In the proposed usage-based pricing algorithm (Figure 1), prices optimization is performed for a single critical resource link in a SP's network. Such a link usually does not behave badly all the time, but only under certain worst-case conditions. On the observed link, the total number of users is N . For each user, bandwidth and price parameters, representing QoS and QoE respectively, are parts of the SLA. Each user gives his parameters of desired bandwidth and maximal price that can't be changed during the agreement period. The bandwidth allotment to user i is denoted as θ_i^* and that is his best response to the price SP determined. The algorithm can be performed for scenarios with different number of service classes in order to optimize bandwidth usage, price per bandwidth unit and a total capacity of the critical link in the network.

There are S rounds in total and in each round s , l_s iterations are performed, where $s = 1, 2, \dots, S$. Each round s consists of several iterative steps. The algorithm, shown in Figure 1, converges quickly after few tens of rounds. Optimization is

Figure 1. Pricing algorithm

performed for each service class j . The algorithm begins when the provider assigns an initial price, M^0 for each service class j . The initial price can be set either randomly or based on historical data. BMS simulates users' behavior in a manner that for each user requiring a certain service class, calculates the desired bandwidth and forwards the data to the provider. The provider then checks whether all user requirements can be met with the existing capacity and if the answer is yes and if the facilities are not used enough, it proceeds to a new iteration with lower prices. In case that requests exceed the network capacity, next iteration is performed with higher prices. In this fashion, users' responses are adapted to the state of network capacity utilization. A round ends when satisfactory utilization of the network capacity is achieved (over 90%). In each round different values of the network capacity are adopted as well as different values of the initial price for each service class. The price offered by the SP, which maximizes his revenue along with the best response bandwidth of each user constitutes the Stackelberg equilibrium (Radonjic & Acimovic-Raspopovic, 2010). In this manner, revenue, as a significant aspect of QoBiz can be improved.

FUTURE RESEARCH DIRECTIONS

In order to provide the appropriate incentives for providers, suitable business and pricing models need to be designed. QoBiz stands out as a significant concept which deals with the financial aspects of service provisioning. For QoBiz evaluation, it is essential to consider service demand, price structures and revenue trends. The need for new pricing solutions that coordinate the competing requirements of providers and users in NGN environment is evident.

In future research, new possibilities for solving similar problems of pricing and interconnection between multiple providers in NGN should be considered. A general research direction should comprise market modelling, cost and risk consid-

eration as well as network design. The proposed algorithm can be extended to cover contemporary real market situation in which several service providers compete for users.

Different types of providers should be considered along with quantifying their impact on the price setting and overall QoBiz. More specific research direction could include applying different game models (e.g. repeated/cooperative games, Cournot and Bertrand games) under dynamic and hybrid pricing schemes. Furthermore, future research should be directed towards more precise mapping between QoE and QoBiz parameters.

CONCLUSION

The adoption of an appropriate pricing scheme can significantly affect business operation of a NGN provider. NGNs must be flexible enough to enable the use of different pricing and business models. Growth in demand due to the popularity of NGN applications requires significant investment in infrastructure but brings a negligible return.

Service providers, therefore, strive for a new network model giving priority to managed services whose usage is controlled by a particular pricing scheme. They are searching for ways to brand and bundle new services, achieve operational cost reductions and strategically position themselves in relation to their competition. Many SPs are looking to NGN services as a means to attract and/or retain the most gainful users. In NGN users are expected to choose the SP offering the best price and QoS combination. As a result, SPs operating in the same telecommunication market will end up competing for users by adjusting QoS they offer and the price they charge for their services.

With the aim of telecom provider's QoBiz improvement, in this chapter the model for the service price optimization is proposed. It has been shown that applying responsive pricing scheme along with Stackelberg game, leads to improvement of the SP's revenue, as a significant aspect of QoBiz. The target market for the application

of the proposed model are business users, such as small and medium enterprises. The introduction of the proposed model should be done gradually to the coexistence with the current pricing models.

KEY TERMS AND DEFINITIONS

Dynamic Pricing: The process of allocating the price as a cost per unit of resource consumption and according to level of QoS guarantees provided for the particular service class.

Hybrid Pricing: The process of applying the static price in regular network operation mode while during congestion the dynamic pricing is enforced allowing deviations from contracted traffic profile.

Next Generation Network (NGN): An architectural concept of future telecommunication core and access networks, which assumes transport of all information and services over a common network, typically built around the IP.

Quality of Business (QoBiz): A monetary value that matches the quality of delivered service, expressed through connection of QoS parameters with monetary value within the SLA.

Quality of Service (QoS): A set of service requirements that a network should meet when transferring traffic flows.

Responsive Pricing: A pricing scheme which incorporates feedback generated by a network assuming that users are adaptive to the service price changes.

Service Level Agreement (SLA): A contract between service providers or a service provider and a user, which defines responsibilities of all

contracting parties, QoS guarantees, performance metrics, measurement methods and pricing principles.

Service Provider (SP): A general reference to an enterprise that provides telecommunication services to users.

Stackelberg Game: A strategic game in which at least one player is defined as the leader who can make a decision and commit a strategy before other players who are defined as followers.

N

Information–Centric Networking

Mohamed Fazil Mohamed Firdhous

University of Moratuwa, Sri Lanka

INTRODUCTION

Over the years, the Internet not only has increased in size in terms of the number of devices, users and applications but also in the type of usage. The original Internet was designed for remote host access along with transferring emails from one host to the other (Almagor, 2011). These applications made the Internet architecture predominantly to be host centric where each and every accessible device on the Internet was assigned a globally unique IP address. The invention of world wide web along with the connected invention of the multimedia browser in the 1990s started pushing the Internet towards an information store. With this transformation, users started searching for the device, where the required information is stored and downloading that information onto his or her computer for viewing. This is commonly known as browsing and still based on the host-centric architecture of the Internet.

Over the years, the information dissemination has shifted from the host centric browsing paradigm to a data (content) centric paradigm, where the information is given the prominence over the device that holds it (Hassan, Elbreiki, Firdhous & Habbal, 2015). This new paradigm of information dissemination has led to the popularity of one-to-many and many-to-many distribution and retrieval of information to increase over the host-to-host communication in the Internet (Katsaros, Chai, Wang, Pavlou, Bontius & Paolone, 2014). Presently users are more interested in retrieving information faster from anywhere on demand rather than knowing where it was originally stored or currently retrieved from. This shift has prompted the storing of information in intermediate nodes with better support for mobility.

DOI: 10.4018/978-1-5225-2255-3.ch569

For supporting this paradigm shift in information retrieval, many incremental solutions in terms of overlay networks have been proposed and implemented over time (Pandey, Garg & Gore, 2012). Though these solutions could meet the requirement of the time, they did not alter the host centric nature of the Internet architecture. Hence they could not overcome the inherent shortcomings of the host centric architecture resulting in issues with scalability, security, mobility and manageability. The continuous minor modifications in terms of patches and incremental solutions has made the Internet architecture more complex and vulnerable leading to a less-flexible architecture with limited manageability. All these has led to the demand for a design for totally new clean slate architecture that can meet the current as well as the future requirements of an information intensive world. In this regard, many independent projects have been initiated by researchers throughout the world. Though the names and finer implementation details of many of these projects differ from each other, many of the important attributes are either common or shared including assumptions, objectives and architectural properties (Hassan et al, 2015; Ahlgren, Dannewitz, Imbrenda, Kutscher & Ohlman, 2012). Paul, Pan and Jain (2011) have discussed many of the projects in detail highlighting the salient features of them along with the experimentations carried out for validating the claims put forward by the researchers.

In this chapter, the author takes a critical look at emerging networking paradigm of Information Centric Networking (ICN) that has been proposed for overcoming the shortcomings of the current Internet architecture. The main focus of the chapter will be features of the proposed ICN architecture with special emphasis on naming,

addressing and routing along with the challenges and requirements that need to be addressed for the development of ICN.

BACKGROUND

The information-centric networking (ICN) is a term coined for identifying the multiple projects carried out by several researchers all over the world for coming up with the future safe Internet architecture while serving the current demand for seamless distribution of information on demand. The architecture of the proposed networking paradigm is to overcome the shortcomings of the present day Internet including security of information and hosts, support for mobility multicast delivery of information, scalability and quality of service guarantees demanded by different users (Ghodsi, Shenker, Koponen, Singla, Raghavan & Wilcox, 2011). The proposed architecture leverages in-network caching, i.e., replication of information in networking devices such as routers, multiparty distribution of information through replication and user interaction models decoupling senders and receivers ultimately achieving a networking architecture that is more resilient to disruptions, failures flash-crowd effects happening in the networks. The some of the prominent projects carried out with the above mentioned objectives include Data-Oriented Network Architecture (DONA), Publish-Subscribe Internet Routing Paradigm (PSIRP) currently known as the Publish-Subscribe Internet Technology (PURSUIT), Network of Information (NetInf) designed as part of the Design for the Future Internet (4WARD) project and currently known as the Scalable and Adaptable Internet Solutions (SAIL), Content-Centric Networking (CCN) currently absorbed into the Named Data Networking (NDN) project, Content Mediator Architecture for Content-aware Networks (COMET) and Delay Tolerant Networking (DTN) (Koponen, Chawla, Chun, Ermolinskiy, Kim, Shenker, Stoica, 2007; Dimitrov & Koptchev, 2010; Dannewitz, Kutscher,

Ohlman, Farrell, Ahlgren, & Karl, 2013; Jacobson, Smetters, Thornton, Plass, Briggs & Braynard, 2009; García, Beben, Ramon, Maeso, Psaras, Pavlou, Wang, Sliwinski, Spirou, Soursos, Hadjioannou, 2011; Fall, 2003). The DTN has been based on a message oriented architecture used along with information-centric addressing and routing concepts.

Concepts of Information-Centric Networking

The ICN paradigm is founded on the idea of production and consumption of information based on user interest. Under ICN, the principle objective of the network is to expose, find and deliver information rather than the reachability of end-hosts and the maintenance of conversations between them (Almeida & Lourenco, 2012). The ICN paradigm mainly consists of two functional parts. They are namely the information dissemination or exposure and information retrieval. Thus the network is assumed to consist of interconnected pieces of information commonly known as content, information or data objects. The content can be of any type including an email, static or user generated data, real time media streams, online videos and music, more complex interactive multimedia communications, or even devices used for network management. Objects can be organized into clusters depending on the requirements to define social relationships or some ontology between them. They can also be mutable, combined or aggregated to form new objects. All these objects are addressed using names for the purpose of identification and routing while managed by applications or services at a upper middleware level. The object names are globally unique and independent of the location where they are stored.

Figure 1 shows the content advertisement and retrieval process in the information centric networks. The creator of any information who is commonly known as the publisher starts the process by advertising the availability of the content in the network without knowing who may be interested

Figure 1. Content advertisement and retrieval process in ICN (Almeida & Lourenco, 2012)

in the said content. Similarly, a receiver known as a subscriber or consumer may also declare its interest on certain quantity without knowing the creator or the current holder of the content in the network. When a receiver's intention matches a published information object, the network initiates a delivery path between a sender and the receiver of the content. Once the delivery path has been established, the content retrieval process would be begun for the receiver. As shown in Figure 1, an information delivery path is generally made up of two end points and several middle nodes. One of the end points is always the receiver who expressed its desire for the contents to the network while the other end point is the sender node that holds a copy of the information object. Hence the sender node need not always be the original creator of the information object but any node that holds (caches) a copy of the information object. Hence in ICN, the match interest rather than the locatability of the end points dictates the establishment of communication. The ICN connects the producers of information to consumers of that information disregarding the underlying hosts. Hence, for increasing the availability of information, dynamic in network caching is enabled in ICN. This in network caching not only improves the availability of information but also reduces the

network latency between the request and response, enables the faster reliable and scalable delivery with improved bandwidth usage reducing congestion. An intermediate router in the delivery path between the sender and receiver may cache the content objects so that the subsequent requests for the same content can be served rapidly by the router itself. This way, routing in ICN consists of finding and delivering copies of information objects from the most efficient location in the network rather than locating the host where it was published originally.

When information is retrieved from a cache rather than from the original source, it is important that the receiver must be provided with guarantees that the cached content indeed came from the original source in the first place. In order to satisfy this requirement, ICN embeds trust directly onto the contents rather than the nodes hosting them. This enables users to verify the quality of the content immediately eliminating the host related threats and vulnerabilities.

Naming of Information Objects

As information rather than hosts plays the central role in information centric networking, naming them with globally unique identifiers is the key

to the success of the entire paradigm. Once an information object is assigned with a globally unique name, it can be addressed and located in the network by users providing the name before the delivery path is created. The naming in ICN not only provides the contents with uniquely identifiable identifiers, but also includes other important properties such as pertinence, usability, scalability and security (Wong & Nikander, 2010). Due to the use of content caching and replication in ICN, name to address mapping creates a one-to-many relation.

Properties of Naming

Everything that is accessible in a network is considered information in ICN (van Adrichem & Kuipers, 2013). The objective of naming in ICN is not only to uniquely identify information objects in the network, but also to include important properties such as pertinence, usability, scalability and security.

- **Uniqueness:** Information objects need to be named in a globally unique fashion in the network. This is required to identify the contents and route them by using their name.
- **Persistence and Location-Independence:** The name needs to be invariant and independent of the location of the host that stores it. Content may generally be replicated or moved from one host to another within the network without service disruption, provided that the provider continues to serve it.
- **Usability and Scalability:** As a network of information, it would be possible to have a large number of data objects in the network where the objects are interconnected with each other and may have multiple interdependencies between them. Furthermore, objects may not be necessarily static and can be mutable. Thus, the naming scheme must not only be scalable but also be us-

able for dynamic objects. The scheme should also allow the deletion of objects automatically through some mechanism such as TTL.

- **Security:** ICN embeds security directly into the content without assuming trust on users or securing the communication channels. Content-based security ensures a cryptographic binding between content and its name to enable information objects to self certify themselves. This binding generally consists of a hash of the information provider's private key in the name of the information object. This allows the authentication of the information provider by creating a signature of the information object using the provider's private key that can be verified with its self-certified public key sent as metadata along with the information object. Confidentiality and integrity of the information are also guaranteed by a public key encryption. An important issue that needs special attention in this self-certification of information is the revocation of information objects when the public key is compromised or information is updated.

The naming schemes used in ICN can be divided into two types based on their structure (Vasilakos, Li, Simon & You, 2015). They are namely, hierarchical and flat naming architectures. Each naming structure has its own advantages as well as disadvantages. The hierarchical naming structure is similar to that of classless inter-domain routing structure of IP addresses. The IP addresses can be aggregated into prefixes performing either longest or shortest match. Similar to domain name systems used in IP networks, hierarchical names used in ICN can also be aggregated and extended (Jacobson et al., 2009). This helps to improve security and authenticity of the provenance of content that is useful in digital rights management. The unique names thus developed are human readable as well as used directly for routing contents

from source to destination. However, the binding between hierarchical names and administrative domains compromises the persistence of information objects. On the other hand, the flat naming structure is not suitable for aggregation but enables easier and faster DHT-like lookups (Stoica, Morris, Karger, Kaashoek, & Balakrishnan, 2001).

The unique names used in ICN include additional metadata for describing contents (Duval, Hodgins, Sutton & Weibel, 2002). The metadata is important in ICN as it describes the content better. Also it helps users to search and find information using keywords rather than the name itself. The metadata can also be used to establish an association between similar information objects. Metadata can also provide cryptographic inputs to perform more complex security checks on information objects. For example, metadata of an information object may contain the provider's public key combined with a digital signature that helps the users to verify the origin of the information. The network can also use the metadata to perform QoS guarantees on information objects, especially for real-time streaming multimedia contents. On the other hand, metadata can be defined in such a manner that it provides an efficient method for monitoring the network health by providing the administrators with useful statistics.

Addressing and Routing in Information Centric Networking

Addressing provides the reachability information of the objects in the network by mapping names to hosting locations (Benmohamed, Cole & Doshi, 2011). Routing in ICN has been implemented using two different strategies (Vasilakos et al., 2015). They are undirected name resolution service or the direct name based routing. The name resolution requires one or several centralized servers such as rendezvous points, register servers, trigger points, etc., in the network. The content publications are collected in these servers and they have a global view of all the published information objects and the network topology. When an ICN router wants

to forward a request message, the routing path is calculated in the centralized server by implementing a link state protocol providing the shortest path between the source and destination. On the other hand, the name based routing is directly performed by the ICN routers. Each router contains a local forwarding information base filled with content publication messages. The request forwarding paths are calculated in the local routers using their own forwarding strategies.

FUTURE RESEARCH DIRECTIONS

Many ICN implementations are still in their early stages and do not address all the requirements of a future internet architecture yet (Wang, 2013). The important aspects such as security, QoS considerations, scalability and network management require to be addressed in more detail and comprehensively. The following is brief description of the issues that demand the immediate attention of the research community to make the information centric network a success.

Security

Security is an essential part of any network architecture that aspires to be future safe (Bellovin, Clark, Perrig & Song, 2005). Hence the ICN researchers have also concentrated on security from the beginning. In ICN, instead of securing communication channels, the ICN model enforces security directly on to the information objects by providing for protection of the authenticity of the objects (Abdallah, Hassanein & Zulkernine, 2015). The use of self-certifying naming based on public-key cryptography leaves certain issues such as key compromise, revocation and management to be resolved by external public key infrastructures or the naming scheme itself. For example, CCN recommends for the distribution of keys as a specific type of information objects using the SDSI/SPKI model. In DONA, key revocations for a principal P can be handled by publication of the

form $P:L$ for some reserved name L . Some of the open security issues in ICN that have attracted the attention of researchers include the problems relating denial of service attacks, content poisoning, cache proliferation attacks and, fuzzy pub/sub message flooding or disturbance (Tourani, Mick, Misra & Panwar, 2016; Abdallah et al., 2015). There can be many different solutions to the above mentioned issues, but it may be interesting to investigate how far probabilistic data streaming algorithms integrated into the ICN for enforcing rate limiting or signature analysis on information objects exchanged between users.

Denial of service attacks generally target either the content provider himself or intermediate routers holding copies of information objects. The general nature of the attack is to target a caching router with invalid requests filling the router's pending interest table (PIT) memory. This results in genuine users being prevented from serving due to lack of resources in the routers. Several researchers have proposed solutions to this kind of DoS attack using different theories, mechanisms and techniques as their base. Some of the proposed solutions include queuing theory based approach, modified token bucket algorithm based vanilla algorithms, per-name prefix rate limiting, Poseidon mechanism, maintaining m-lists and statistical hypothesis testing theory based interest flooding detecting (Tourani et al., 2016). Though these solutions could successfully mitigate the effects of DoS attacks under different conditions, assumptions made during the design of these mechanisms limit the general applicability of these mechanisms. Hence this area is still open for further investigation.

Content poisoning attacks target the memory of the content caches and fill them with invalid contents (Tourani et al., 2016). For injecting the network with invalid contents, an attacker must first get the control of one or more content providers or intermediate routers. Once an attacker brings a content provider under its control, it can flood the network with malicious contents forcing the intermediate routers to store them in their

caches. The counter measures proposed include self-certifying interest/data packet helping the routers to verify and validate the contents before storing or forwarding, ranking mechanism for cached content using exclusion based feedback and signature verification techniques. Though these mechanisms help reduce the amount of content poisoning, they put additional burdens on the network and routers increasing the latency and energy consumption. Hence there is still room for coming up with light-weighted schemes for mitigating the effects of this problem.

Cache pollution attack targets the basic premise on which the entire caching mechanism is built on. Popularity of content in the Internet follows Zipf distribution where a smaller number of popular content are requested frequently. Hence these popular contents can be cached in the edge routers reducing the latency and loading on the Internet links saving bandwidth. The attackers exploits this basic premise and request less popular contents more frequently skewing the distribution. This makes caching less effective polluting the cache with less popular contents. The mitigating solutions proposed include *CacheShield*: a mechanism providing robustness against the locality disruption attack, machine-learning based algorithms and detection scheme based on randomness check. Many of the above proposed solutions incur high computation cost at the intermediate routers making them less scalable. Hence opportunities are still there for coming up with more scalable lightweight mechanisms.

Other areas of ICN security that also require the attention of researchers and developers include, secure naming and routing schemes, application level security, privacy and anonymity in ICN and access control.

Quality of Service Considerations

Quality of Service is concerned with the optimal use of shared resources by allocating them among different classes of users meeting their stipulated requirements (Kaur, 2011; Reddy, Hemalatha

& Mubeen, 2014). The principal objective of QoS management is to apply different priority to different data flows increasing the utility of the network while guaranteeing the required level of performance. With respect to other types of networking schemes such as IP and MPLS, ICN is better placed to manage quality of service based on different traffic flows (Al-Naday, Bontozoglou, Vassilakis & Reed, 2014). This advantage is achieved due to the fact that ICN has a knowledge of the information type before it has been located and transported. But different ICN architectures provide different methods for content identification making it difficult to port mechanisms developed for one type to another.

Scalability

Similar to the existing IP based Internet, the ICN would also grow to become a network with billions of devices, users and objects (Ghodsi et al., 2011). Hence the future ICN network would be required to distribute these billions of information objects to billions of users (devices). This creates two important issues with respect to scalability. They are naming scalability and routing (forwarding) scalability (Xylomenos, Ververidis, Siris, Fotiou, Tsilopoulos, Vasilakos, Katsaros & Polyzos, 2014). With the growth of the namespace, it would be extremely difficult to avoid naming conflicts guaranteeing globally unique names. Both flat and hierarchical naming structures would face this infinitely growing namespace problem at one or the other time. The other associated problem is routing as ICN employs name based routing. Hence this still remains an open research area to be solved.

Network Management

Many of the ICN proposals lack network management as part of the core architecture (Almeida & Lourenco, 2012). Not only the original proposals have failed to include network management as a

core concept within the architectures, even the later researches have also paid scant attention to this important area. Eum et al (2015) have proposed to design an ICN architecture within the framework of software defined network (SDN) in order to achieve the combined advantage of both networking schemes. SDN provides the advantage of decoupling network management from the underlying network infrastructure. This lowers the cost and complexity of network management enabling the continuous evolution of the network architecture in a flexible manner. Hence combining both ICN and SDN design principles will achieve a synergy between them supporting efficient dissemination of information providing flexible management framework. Other than the above mentioned proposal, this area has not seen any other contribution. Hence it remains an open area for further research.

CONCLUSION

In this chapter, the author has presented a comprehensive overview of the emerging networking paradigm of information centric networking. ICN aims to overcome the limitations of the current Internet architecture moving away from the host centric model to a data (information) centric model. The chapter presented the design principles of ICN in detail along with the major topics of naming, addressing and routing. Finally the chapter took a look at the open research challenges in the chosen area that needs the immediate attention of the researchers.

KEY TERMS AND DEFINITIONS

Attack: An attempt to gain unauthorized access to, steal, expose, alter, disable or destroy computing resources by unauthorized personnel or through unauthorized means.

Content Centric Networking (CCN): A networking paradigm that emphasizes content by making it directly addressable and routable.

Future Internet: A general term coined for describing all the research activities carried out for developing new architectures for the Internet with the view of overcoming its shortcomings.

Information Centric Networking: An approach to evolve the Internet infrastructure to identify named information independently of the distribution channel by introducing uniquely named data as a core Internet principle.

Metadata: A set of data (information) used for describing the actual user data.

Named Data Networking (NDN): A Future Internet architecture designed with the objective of solving problems associated with contemporary internet architectures.

Network Architecture: A framework for the specification of a network's physical components, functional organization, configuration, operational principles and procedures along with the data formats used.

Publish/Subscribe Paradigm: A messaging scheme where senders of messages known as publishers stores the messages in an intermediary location without sending them directly to specific receivers (subscribers). Subscribers can retrieve these messages from these intermediary nodes as and when required.

Security: Denotes the protective mechanisms including policies, guidelines and algorithms applied to computers, computer networks, users and data stored and transmitted over them.

Interoperability Frameworks for Distributed Systems

José Carlos Martins Delgado
Universidade de Lisboa, Portugal

INTRODUCTION

A system is *distributed* with respect to another if their lifecycles are not dependent, i.e., if one can evolve (to a new version) without having to change, to suspend or to stop the behavior or interface of the other.

Different systems usually need to interact, raising the concept of *interoperability* (ISO/IEC/IEEE, 2010), which literally means the *ability* (of two or more systems) to *operate together*. An *interoperability framework* is a set of principles, assumptions, rules and guidelines to analyze, to structure and to classify the concepts and concerns of interoperability.

What these words really mean largely depends on the domain which the systems belong to, although there is a pervasive, underlying notion that these systems are active, reacting upon stimuli sent by others and cooperating to accomplish higher-level goals than those achievable by each single system.

Interoperability has been studied in domains such as enterprise cooperation (Popplewell, 2014; Rezaei, Chiew, & Lee, 2014), e-government services (Sharma & Panigrahi, 2015), military operations (Hussain, Mehmood, Haq, Alnafjan, & Alghamdi, 2014), cloud computing (Zhang, Wu, & Cheung, 2013), healthcare applications (Robkin, Weininger, Preciado, & Goldman, 2015), digital libraries (Agosti, Ferro, & Silvello, 2016) and metadata (Chen, 2015).

In this article, we adopt a more general perspective, exploring interoperability in the generic context of distributed systems, independently of what they are or which domain is the most rel-

evant to them. The following section describes some of the most relevant existing interoperability frameworks. The section after that one introduces the basic concepts that establish a foundation for interoperability in distributed contexts. Next, a multidimensional interoperability framework is proposed and its advantages discussed. Finally, future research directions are hinted and conclusions drawn.

BACKGROUND

The Open Systems Interconnection (OSI) reference model (ISO/IEC, 1994), constitutes one of the first systematizations of distributed interoperability, considering seven layers (Table 1). This standard deals mostly with communication issues, with the objective of sending data and reproducing it at the receiver. How those data are interpreted by the receiver and how it reacts to the data is left unspecified, encompassed by the topmost layer, Application. However, interoperability must ensure not only the exchange of data but also the meaningful use of information (ISO/IEC/IEEE, 2010), which means that this layer must be detailed.

Table 1 depicts the basic structure of several interoperability frameworks (referred to by acronym or first author) that use this layered approach, establishing a rough horizontal correspondence between layers.

The C4IF framework (Peristeras & Tarabanis, 2006), is based on four layers: Connection (basic use of a channel), Communication (data formats), Consolidation (meaning through semantics) and Collaboration (through compatible processes). It

Table 1. Comparison between several layered interoperability frameworks

OSI (1994)	C4IF (2006)	Lewis (2008)	Stamper (2000)	LCIM (2009)	EIF (2010)	Monfelt (2011)
Application	Collaboration	Organizational	Social world	Conceptual	Political	SWOT
						Cultural
						Ethical
					Legal	Legal
	Consolidation	Semantic	Pragmatic	Dynamic	Organizational	Managerial
				Pragmatic		Organizational
				Semantic	Semantic (includes syntactic)	Adaptation
Presentation	Communication	Syntactic	Syntactic	Syntactic		Application
Session						Presentation
Transport						Session
Network	Connection	Machine	Empirics	Technical	Technical	Transport
Link						Network
Physical Medium			Physical world			Link
						Physical Medium

simplifies the lower levels (distinguishing only connectivity and communication) and refines the application layer, distinguishing information semantics from behavior.

Lewis, Morris, Simanta, and Wrage (2008) proposed a similar framework, with slight differences but with basically the same structure.

Stamper, Liu, Hafkamp, and Ades (2000) applied *semiotics* (the study of signs, stemming from linguistics) to the field of information systems and proposed a semiotic ladder, a layered structure in which each layer builds on the previous one (just like a ladder) in an increasing level of abstraction and complexity. Besides the usual syntax and semantics, pragmatics was used to refer to the interaction context and the effect caused by the reception of a message by a receiver. Empirics refer to the lower levels using the physical world, which details are well established and become less relevant to the understanding of interoperability as a whole. The social world tackles the higher levels, in which people become more involved.

Wang, Tolk, and Wang (2009) described the LCIM framework, which follows the semiotic

ladder in essence, with the interesting addition of a dynamic layer that considers evolution along the system's lifecycle.

The European Interoperability Framework (EIF, 2010) was conceived as a broad framework for the interoperability of public services and establishes four main interoperability levels (legal, organizational, semantic and technical), with an upper political context that should ensure compatible visions and aligned priorities.

Monfelt, Pilemalm, Hallberg, and Yngström (2011) further refined the social layer of the semiotic ladder and extended the basic OSI reference model with another seven layers, to take care of higher-level issues, such as risk (SWOT analysis) and dependencies on social and organizational aspects concerning cultural, ethical and legal values, as well as existing administrative and managerial issues. The organizational layer pertains to the pragmatics of the message (its effects in the interaction context) and the adaptation layer pertains to the semantics of the message, adapting the new layers to the technical layers provided by the OSI model.

Other interoperability frameworks, particularly those conceived for complex systems, such as enterprises, try to complete the scenario by considering more than one dimension of interoperability, so that aspects of a different nature can be tackled in an orthogonal way. For example, the lower layers in Table 1 have a clear operational nature, but the higher layers are more conceptual and as such should be dealt with in a previous stage of the systems' lifecycle. Table 2 gives a brief description of these multidimensional frameworks.

Even with multidimensional frameworks to capture the various aspects of interoperability, there is the need to perform an assessment of to which degree systems are interoperable. Doing this on every dimension and aspect is complex and reduces the global perception of the interoper-

ability goals. Therefore, a typical approach is to perform a qualitative assessment in a single scale, by considering the maturity of the systems and of their relationship in terms of interoperability. This involves establishing a set of levels that give a qualitative indication of how far in the abstraction scale has interoperability been considered.

In fact, several frameworks are defined more in terms of the maturity of systems' interoperability than on layer structure or dimensions. Table 3 illustrates the classification of several of these frameworks. Each framework has its own slant and terminology, but overall they possess rather similar structures, ranging from a complete lack of interoperability (level 0) to full integration (level 4).

Table 2. Several multidimensional interoperability frameworks

Framework	Dimensions	Description
SOSI (Morris, Levine, Meyers, Place, & Plakosh, 2004)	Operational	Issues between existing systems that need to interoperate, such as lack of information and non-intuitive user interfaces
	Programmatic	Interoperability between computer applications and solutions
	Constructive	Architectural issues such as data schema interoperability
AIF, ATHENA Interoperability Framework (Berre et al., 2007)	Conceptual	Integration models at the levels of enterprise/business, process, service and information/data
	Application	Methodology with methods to support the development of interoperability projects
	Technical	Implementation basis around technologies such as BPEL, Web Services and XML
FEI, Framework for Enterprise Interoperability (ISO, 2011)	Concerns	At the levels of business, processes, services and data
	Barriers	Difficulties in making systems interoperable (conceptual, technological and organizational)
	Approach	Plan to overcome the barriers. Can be organized in three ways: • Integrated (a common format is used by all systems); • Unified (common goals and semantic mapping); • Federated (common goals and ontology are possible, but each system must adapt to others dynamically, without any imposed model).
ULS Interoperability Framework (Ostadzadeh, Shams, & Badie, 2015)	Abstract	Six classical questions of the Zachman framework (O'Rourke, Fishman, & Selkow, 2003), in the interoperability context: what, how, where, who, why, when
	Perspective	Layered interoperability concerns (contextual, conceptual, logical, physical and out-of-context)
	Barriers	Considers the dimensions of SOSI (Operational, Constructive and Programmatic) as barriers and extends them with cultural barriers
ENSEMBLE European Project (Charalabidis, Lampathaki, & Jardim-Goncalves, 2014)	Domains	Interoperability problem space: social, applied and formal sciences
	Areas	Scientific areas underlying interoperability: data, process, rules, objects, software, cultural, knowledge, services, social networks, electronic identity, cloud and ecosystems
	Elements	Scientific interoperability elements: semantics, models, tools, orchestration

Table 3. Interoperability maturity levels of several frameworks

Level	Typical meaning	LISI (C4ISR, 1998)	OIM (Fewell & Clark, 2003)	OIAM (Kingston, Fewell, & Richer, 2005)	MMEI (Guédria, Chen, & Naudet, 2009)
4	Capable of dynamically adapting to partner's intent	Enterprise	Unified	Dynamic	Adapted
3	Capable of meaningfully exchange semantic content	Domain	Combined	Open	Organized
2	Capable of invoking functionality at the syntax level (common formats)	Functional	Collaborative	Accommodating	Aligned
1	Basic connectivity at the message level	Connected	Ad hoc	Amenable	Defined
0	Unable to interact	Isolated	Independent	Static	Unprepared

THE FOUNDATIONS OF INTEROPERABILITY

Defining the Meaning of Interoperability

Figure 1 illustrates the most basic interoperability scenario, with a system in the role of *consumer* and another in the role of *provider*. The consumer sends a request to the provider, which reacts to it, typically executing some actions and eventually sending back a response to the consumer. System interaction does not have to be message based. A file written by the consumer and later read by the provider will have the same effect. This basic scenario can be extended by composition. The same system can act as a consumer and as a provider, in bidirectional interactions, or several

systems can take part in a multipartite interaction (a *choreography*) towards some common goal.

The 24765 standard (ISO/IEC/IEEE, 2010) provides one of the most cited definitions of interoperability: “The ability of two or more systems or components to exchange information and to use the information that has been exchanged”. This means that interoperability involves more than mere communication. Interacting systems must be able to understand the information they receive, so that they can use it, at various levels of abstraction, as already detailed by Table 1.

Table 4 provides our own proposal for the interoperability layers, which constitutes the first dimension of our interoperability framework. The goal with respect to existing frameworks is to provide an additional systematization of the upper interoperability layers.

Figure 1. A simple request-response interaction between two systems

Table 4. Layered perspective of interoperability

Category	Layer	Main artifact	Description
Symbiotic (purpose and intent)	Coordination	Governance	Motivations to have the interaction, with varying levels of mutual knowledge of governance, strategy and goals
	Alignment	Joint-venture	
	Collaboration	Partnership	
	Cooperation	Outsourcing	
Pragmatic (context and reaction effects)	Contract	Choreography	Management of the interaction context and of the reaction effects of the interactions at the levels of choreography, process and service
	Workflow	Process	
	Interface	Service	
Semantic (meaning of content)	Inference	Rule base	Interpretation of a message at the levels of rule, known system components and relations, and definition of concepts
	Knowledge	Knowledge base	
	Ontology	Concept	
Syntactic (notation of representation)	Structure	Schema	Representation of system components, in terms of composition, primitive components and their serialization format in messages
	Predefined type	Primitive resource	
	Serialization	Message format	
Connective (transfer protocol)	Messaging	Message protocol	Lower-level formats and network protocols involved in transferring a message from the context of the sender to that of the receiver
	Routing	Gateway	
	Communication	Network protocol	
	Physics	Media protocol	

Partial Interoperability: Compliance and Conformance

The 24765 standard (ISO/IEC/IEEE, 2010) actually provides three definitions of interoperability, stemming from previous and now superseded standards. The second definition relevant to this article is: “The capability to communicate, execute programs, and transfer data among various functional units in a manner that requires the user to have little or no knowledge of the unique characteristics of those units”. Here the emphasis is on decoupling, meaning that interacting systems need not be designed for a full match, as long as some characteristics support the interaction, and can evolve independently, as long as these characteristics are maintained. This leads to the concept of *degree of interoperability*, an indicator that expresses how much of the functionality or characteristics of a system can be accessed by another, ranging from none to the full set.

Consider Figure 2, an extension of the scenario of Figure 1, in which system *A* (the consumer) and system *B* (the provider) have been designed independently. *A* was designed to interact with a provider *X* and *B* was designed to expect a consumer *Y*. Having *A* interoperable with *B* involves two conditions (Delgado, 2014):

- Compliance (Tran, Zdun, Oberortner, Mulo, & Dustdar, 2012). *A* must *comply with Y*, which means that *A* must satisfy all the *requirements* of *Y* in order to send requests to *B*. Therefore, *A* can use *Y* to reach *B* (“Use” arrow), without noticing the difference;
- Conformance (Khalfallah, Figay, Barhamgi, & Ghodous, 2014). *B* must *conform to X*, which means that *B* must fulfill all the *expectations* of *A* regarding the effects of requests it sends to *X*. Therefore, *B* can effectively replace (take the form of) *X* without *A* noticing it (“Replace” arrow).

Figure 2. Compliance and conformance. X is how A views provider B . Y is how B views consumer A . X and Y are specifications, not actual systems

Partial interoperability can be achieved by *subsumption*, with the set of provider's features that A uses as a subset of the set of features offered by B , and as long as B (or another system that replaces it) supports the expectations of A regarding the reactions to requests.

In many cases, systems are made interoperable by design, i.e., conceived and implemented to work together (as in Figure 1). When systems are complex (such as enterprises) and evolve in an independent way, ensuring interoperability is not an easy task. A typical and pragmatic solution is to resort to Web Services and XML data, sharing schemas and namespaces, but this entails a high degree of coupling since it involves the entire interface of the provider.

The notion of partial interoperability introduces a different perspective, stronger than similarity but weaker than commonality (resulting from using the same schemas and ontologies). The trick is to consider only the intersection between what the consumer needs and what the provider offers. If the latter subsumes the former, the degree of interoperability required by the consumer can be granted, regardless of whether the provider supports additional features or not.

The Role of System Lifecycle in Interoperability

Compliance and conformance apply not only to message-based interactions, in both content (syntax and semantics, including ontology) and protocol (flow of messages and their effects), but also to non-operational relationships, such as strategy alignment and regulatory compliance. This acknowledges the fact that interoperability is not merely about the operation stage of the system's lifecycle but starts much earlier, in the conception stage. After all, what happens in the operation stage is a consequence of what has been conceived and designed.

Figure 3 expresses this perspective by depicting information on two interacting systems, each schematized in two dimensions, lifecycle stages (horizontally) and interoperability abstraction layers (vertically), which express the detail at which interoperability is considered (see Table 4).

Figure 3 should be interpreted as follows:

- The lifecycles are simple, with just four stages, but they could easily be refined by

- detailing each of these stages while maintaining the whole interoperability rationale;
- All the layers of abstraction of interoperability should be considered in every stage. However, it is only natural that the method used to evolve the system along its lifecycle considers interoperability at an abstract layer in the initial stages and at full detail in the operation stage;
- For simplicity, we consider only the most relevant concept in each category of abstraction layers of interoperability (first column of Table 4: Intent, Context, Meaning, Notation, and Protocol), instead of each layer individually;
- There must be compliance (in the consumer to provider direction) and conformance (in the provider to consumer direction) in each corresponding cell (in a given stage and abstraction layer) of both interacting partners. This is illustrated in detail by Figure 3 in the operation stage only. However, the same should happen in other stages (the dashed arrows at the top of the figure indicate this). The rationale for this is twofold:

 - Partners must be interoperable at each abstraction layer of interoperability, be it at the intent layer (one must understand and accept what the other intends to achieve), at the meaning layer (interoperable ontologies and semantic relationships) or at the basic protocol layer (there must be message connectivity);
 - Each stage is a consequence of the previous stage, in a model-driven fashion. For systems to be interoperable at operation time, their conception and design must also be made interoperable;
- The evaluation stages need not necessarily be made interoperable. Each system can evaluate its design independently, although the specifications for interoperability must not be overlooked and need to be considered in the context of the partners' relationship.

Figure 3. System lifecycle combined with interoperability abstraction layers

A MULTIDIMENSIONAL INTEROPERABILITY FRAMEWORK

Figure 4 depicts a domain-independent and multidimensional interoperability framework, conceived generically for any type of systems.

The two main structuring dimensions are the Lifecycle (with its stages) and the Interoperability (with its abstraction layers), forming the plane shown in Figure 3. Other aspects, more specific or more domain-oriented, are introduced by a Concerns dimension, expressed in Figure 4 by one plane for each concern, such as the functional specification and legal, cultural and security issues.

The plane formed by the Concerns and Interoperability dimensions (in each stage of the lifecycle) corresponds to considering all aspects of the relationship with a partner in every abstraction layer, while developing the system. The plane formed by the Concerns and Lifecycle dimensions corresponds to considering the entire development of a partner, in all stages and aspects, for each layer of abstraction of the relationship between partners.

This framework is extensible, not only by considering additional concern planes but also by the ability to promote a concern to a full-fledged dimension, if its relevance and applicability breadth justifies that (if it has a variability that

Figure 4. A multidimensional interoperability framework

is relevant across the entire span of existing axes and refers to issues orthogonal to those dealt with by other axes).

A development method is needed to exercise this framework, from the origin of the axes, where everything is conceptual and abstract, to a point in this multidimensional space in which everything is defined and concrete. This method can vary, according to the path chosen along the dimensions (breadth-first, depth-first, and so on) to reach that point, but typically an iterative approach is followed, by progressing along all dimensions, in successive versions of increasing detail (as Figure 3 had already hinted). Figure 4 illustrates two versions of this evolution.

It should be noted that, although the Lifecycle-Interoperability plane shows two partners, their development is coupled only inasmuch as required by compliance and conformance. This illustrates that the development of systems is only partially independent. If interoperability is required, some degree of coupling and co-development is unavoidable.

The main advantages of this multidimensional framework with respect to those mentioned in Table 2 are:

- Generic and domain independent, by considering interacting partners as systems of any kind and complexity. Many other frameworks tend to favor some domain, such as enterprise engineering or military environments;
- Recursive, in the sense that it can be applied to a system or recursively to its components;
- Based on system development lifecycle, considering all stages, instead of just adding interoperability to existing systems;
- System coupling based on partial interoperability, expressed by compliance and conformance;
- Extensible, by promoting a specific concern (e.g., security) to an axis on its own right;

- Clear separation of framework from method. Most frameworks include an approach, which is part of the method, but these are different concepts that should be kept separate (e.g., to allow different methods to exercise a given framework).

FUTURE RESEARCH DIRECTIONS

The CEN EN/ISO 11354-1 standard (ISO, 2011), sets the trend in interoperability consolidation by standardization. However, we cannot expect this standard to apply to all domains and other interoperability standards will appear.

The ENSEMBLE project (Charalabidis, Lampathaki, & Jardim-Goncalves, 2014) has spurred a movement towards the establishment of enterprise interoperability as a science and the development of an interoperability body of knowledge (Jardim-Goncalves, Grilo, Agostinho, Lampathaki, & Charalabidis, 2013).

The interoperability framework described in this article can make a contribution to this effort, although it needs to be improved and made more complete, in several ways:

- The Concerns axis needs to be detailed, to include a better perspective of relevant concerns such as security and common domain-specific aspects and problems, such as those uncovered by the ENSEMBLE project;
- Compliance and conformance are basic concepts, applicable to all domains and layers of abstraction and complexity, but need formalization and definition of their exact meaning in each of the abstraction layers of interoperability of Table 4;
- A method to exercise the framework needs to be devised, with a comparative case study with other interoperability methods, namely those promoted by relevant bodies, such as the European Interoperability Framework (EIF, 2010) or standardized, such as the Framework for Enterprise Interoperability (ISO, 2011).

CONCLUSION

The world is increasingly both distributed and interconnected. Interoperability is crucial and standards are not enough to ensure cooperation (Lewis, Morris, Simanta, & Wrage, 2008). Interoperability frameworks provide a classification structure to organize interoperability concerns, and several frameworks have been proposed, both single and multidimensional.

This article briefly described some of these frameworks and argued that, instead of establishing a framework according to the main issues in a given domain (such as e-government or healthcare), a set of foundational interoperability concepts (such as lifecycle, compliance, conformance and concerns) is enough to define a domain-independent framework, with truly orthogonal dimensions and a clear separation from a method that uses it. This framework and its dimensions were described.

Nevertheless, interoperability seems to constitute, by its very nature of conflicting goals, an unsolvable problem:

- Systems want to interact with others, but not to be dependent upon them;
- Sharing is good (and necessary), but privacy and information hiding is even better;
- Standardization is good but enforced normalization can hamper differentiation between providers.

The compromise is to apply the principle of least coupling, by which systems should interact by using just the minimum possible set of features. Compliance and conformance are the basic concepts that drive the applicability of this principle and an interoperability framework (such as the one described in this article) constitutes the basic tool to achieve it.

KEY TERMS AND DEFINITIONS

Choreography: Contract between two or more systems, which establishes how they cooperate to achieve some common goal.

Compliance: Asymmetric property between a consumer C and a provider P (C is compliant with P) that indicates that C satisfies all the requirements of P in terms of accepting requests.

Conformance: Asymmetric property between a provider P and a consumer C (P conforms to C) that indicates that P fulfills all the expectations of C in terms of the effects caused by its requests.

Consumer: A role performed by a system A in an interaction with another B , which involves making a request to B and typically waiting for a response.

Dimensions of Interoperability: Organization of an interoperability framework that defines several axes, or dimensions, of orthogonal interoperability concerns. This allows a better specification of an interoperability problem than by using just a single dimension of interoperability layers.

Distributed Interoperability: Interoperability between systems that have independent lifecycles. This means that they can evolve (to a new version) without having to change, to suspend or to stop the behavior or interface of the other. Distribution does not necessarily imply geographical dispersion.

Interoperability: The ability of a consumer C to be partially or fully compatible with a provider P . By composition, it can also refer to multilateral compatibility between several systems, interacting in the context of some choreography.

Interoperability Framework: Set of principles, assumptions, rules and guidelines to analyze, structure and classify the concepts and concerns of interoperability.

Layers of Interoperability: Organization of interoperability concepts and concerns along a single dimension, in layers of monotonically varying degree of complexity and abstraction.

Provider: A role performed by a system B in an interaction with another A , which involves waiting for a request from A , honoring it and typically sending a response to A .

Neural Networks and Their Accelerated Evolution From an Economic Analysis Perspective

INTRODUCTION

The expression ‘neural networks’ is a relatively new one in the history of universal science. It represents an automated system, similar to the human brain and works under its corresponding rules, leading to substantial outputs, based on the economic phenomenon analysed. ANN is a separate section of Artificial Intelligence, which in turn designates a research area in Computer Science. Neural networks, as a component of Artificial Intelligence, deal with the processing of specific data structures, learning and classification data algorithms, based on human brain operation.

From the perspective of recognition models, neural networks can be considered an extension of various conventional techniques that have been developed during several decades, namely conventional recognition model like the statistical model that is considered essential for a clear understanding of neural networks. Extensions of this topic can be found in many articles about statistical recognition models that laid the statistical foundations of neural networks: Duda and Hart (1973), Hand (1981), Devijer and Kitter (1982), Fukunaga (1990), Ripley (1994), Cheng and Titterton (1994).

BACKGROUND

The history of neural networks can be divided into five stages: the beginning of neural networks; the golden age; the quiet years, years of renewed enthusiasm showing the interaction between biological experimentation, modelling and computer stimulation, with hardware implementation, finishing with the fifth stage – permanent development.

1940-1950: The Beginning of Neural Networks

In 1943 the neuropsychologist Warren McCulloch and the mathematician Walter Pitts published the paper “A Logical Calculus of the Ideas Immanent in Nervous Activity”, laying the foundations of neural networks. The first precursors of computers were developed as true electronic brains, being supported by Konrad Zuse, who calculated ballistic trajectories using manual procedure. In 1941, in Berlin, at the German Institute for Aviation Research, Z3, Konrad Zuse (1993) designed an electromechanical computer, which was the first programmable computing machine, fully automated, being used to perform statistical analysis for wings vibrations.

DOI: 10.4018/978-1-5225-2255-3.ch571

Warren McCulloch and Walter Pitts (1947) indicated a practical field for the application and recognition of spatial models by neural networks.

Another researchers like Norbert Wiener and von Neumann, showed that research on the human brain design using computers could be a very interesting thing.

In 1949, Donald Hebb wrote *The Organization of Behaviour* and showed that neuronal connection is becoming stronger as it is used, being a fundamental concept for the learning process of a network. Moreover, Hebb developed the rule that bears his name, and which is the basis for almost all of neuronal learning procedures. Hebb could not postulate this rule due to the absence of neurological research, the only able to confirm this result.

Karl Lashley (1950) argued, as a neuropsychologist, that the storing of information by the brain is designed as a distributed system. His thesis was based on experiments on rats.

1950-1960: The Golden Age of Neural Networks

The most remarkable event of that time was the building of the first neuro-computer (The Snark) by Marvin Minsky (1951), which was able to adapt automatically the weights. Snark operated successfully from a technical point of view, but never exercised extremely interesting functions of information processing.

In 1956, the Dartmouth Summer Research Project on Artificial Intelligence has provided a momentum for artificial intelligence and implicitly for neural networks. The next years, John von Neumann proposed the functioning of a simple neuron by using telegraph relays or vacuum tubes.

At the same time, in 1956, Frank Rosenblatt, a neurobiologist at Cornell, started to study about the perceptron. Rosenblatt, as the founder of neural computation, besides inventing the perceptron, was mostly interested in pattern recognition and wrote a book about neural computing, entitled *Principles of Neurodynamics*. This field was developed dur-

ing 1967-1968 through the efforts of Frank Rosenblatt and his co-workers, who designed the first successful neuro-computer, the Perceptron Mark I, which was able to recognize simple average sized numbers of about 20x20 pixels, through an image sensor. For the electromechanical part, they used 512 potentiometer engines, each of them having a variable weight. A bit later, Widrow and Hoff (1960) were distinguished by their studies made by following similar steps.

In 1958, Rosenblatt introduced a simple single-layer artificial neural network, which later will be called perceptron.

In 1959, Rosenblatt described different versions of the perceptron, and verified the perceptron convergence theorem, describing neurons layers that imitate the retina, threshold switches and a learning rule by adjusting the connection weights.

In 1960, Widrow and Hoff have developed the ADALINE models (*ADaptive LInear NEuron*) and the MADALINE models (*Multiple ADaptive LInear Elements*). MADALINE, a quick and accurate adaptive learning system, was the first neural network used to solve a real problem and is still widely used especially in air traffic control. Also, they are the authors of Widrow-Hoff rule or delta rule used in learning process.

1960-1980: The Quiet Years of Neural Networks

Steinbuch (1961) introduced technical achievements for the associative memory, which can be seen as a predecessor for today's neural associative memories. He also described concepts for neural techniques by analysing their possibilities and limitations.

In his book "Learning Machines", Nilsson (1965) has given an overview of the progress and achievements of this period of research in neural networks. He took into consideration the basic principles of self-learning and therefore were discovered the intelligent systems. Later, this assumption proved to be an overstatement, but at that time it provided a very popular area of research.

In 1969, Minsky and Papert published an accurate mathematical analysis of the perceptron, and showed the limitations of the single layer perceptron in the book *Perceptrons*. The analysis demonstrated that the perceptron model is not able to represent several important issues, such as the XOR problem and linear separability. However, research in neural computation area has continued, particularly in fields as adaptive signal processing, pattern recognition and biological modelling.

Kohonen (1972) introduced a linear association model for associative memory. The same year, a similar model was independently introduced by the neurophysiologist Anderson (1972).

Marsburg (1973) used a nonlinear neuron model, with a better performance regarding its conformity to reality.

In 1974, neural networks began to be widely used, with the introduction of the back propagation of signal algorithm (“backpropagation”). The algorithm was initially described by Paul Werbe (1974) and further developed by Rumelhart, Hinton and Williams (1986).

In fact, many of the leaders of neural networks area started to publish their studies during 1970-1980: Amari (1967), Fukushima (1980), Grossberg (1972, 1976). In these articles, numerous neural models were mathematical analysed. They were the ones who put neural networks on a firm position and paved the way for the recovery of this field.

Moreover, Grossberg studied the problem of keeping a neural network capable of learning without destroying already learned associations. Later cooperation with Gali Carpenter (1987) led to development of Adaptive Resonance Theory (ART).

1980-2000: Renewed Enthusiasm

In the early 1980s, many researchers in the field of neural computation have become bold enough to start submitting proposals for developing the neuro-computer area and therefore the applications based on neural networks.

Between 1982-1986, John Hopfield, a physicist with worldwide reputation, became interested in neural networks, and through its numerous conferences in the world, he convinced hundreds of highly qualified scientists, mathematicians and engineers to join the emerging field of neural networks.

Hopfield (1982, 1984, 1985) proposed the bi-directional link in a network, giving birth to recurrent neural networks (ANN Hopfield), which are inspired by the physics laws of magnetism. Also, in 1982, at the conference *Cooperative/Competitive Neural Networks* (US-Japan) was launched the idea of a new generation of computers based on artificial intelligence (first generation – based on electrical switches, second generation – based on transistors, third generation – based on integrated circuits and advanced programming languages, fourth generation – based on codes generators and fifth generation – based on artificial intelligence).

Kohonen (1982, 1989) developed the network theory with unsupervised training (self-organizing), describing characteristics of the self-organizing map, which later will bear his name. Although they were not widely used in technical applications, neural networks slightly regained importance.

Fukushima (1980), Fukushima, Miyake and Ito (1983) introduced the neural model called Neocognitron that can recognize handwritten characters and which was an extension of Cognitron network developed in 1975.

Through the influence of John Hopfield, who convinced many researchers about the importance of the field, and through the publication of back-propagation by Rumelhart, neural networks made a modest progress.

By 1985, the American Institute of Physics began what has become an annual meeting on Neural Networks for computers.

Parker (1985) and Le Cun (1986) rediscovered the learning method for back-propagation of the signal.

Also in 1985, John Hopfield published an article describing a way to find acceptable solu-

tions for Travelling Salesman problem by using Hopfield nets.

In 1986, Rumelhart, Hinton & Williams introduced the back-propagation of error learning procedures, as a generalization of the delta rule. The non-linear-separability problem could be solved by multilayer perceptron. Since then, research development in this field has been almost explosive.

Also in 1986 with the publication of “PDP books” (Parallel Distributed Processing, Volumes I and II), edited by Rumelhart and McClelland, this area has exploded.

In 1987, the Institute of Electrical and Electronics Engineer (IEEE) organized the first International Conference on Neural Networks held in San Diego, and there was created the International Neural Network Society which gathered over 1800 participants.

In 1988 was founded the journal of Neural Networks by INNS, followed by Neural Computation in 1989 and by the IEEE Transaction on Neural Networks in 1990.

In 1989, at the meeting based on neural networks role in the defense strategy Bernard Widrow told his audience that “they were engaged in World War IV, “World War III never happened” where the battlefields are world trade and manufacturing”.

In 1990 the US Defense Department for Small Business Innovation research program named 16 topics specific to neural networks and another 13 topics that include the possible use of neural networks. In the same year, the theory on artificial neural networks based on radial activation functions (ANN-RBF) was developed.

2000-2016: Years of Permanent Development

In 2000, the studies highlighted the overall strength of NN and of the vector support machines. After that, the utility of neural networks has significantly broadened the area. Therefore, artificial

neural networks were used for: economic forecasts (at micro and macro level), shapes detection in biological pictures, chemical problems, solving hydrological problems, bioelectrical impedance analysis for body composition assessment for old people (Hsieh, Chen Lu, Huang Chen, 2012), nuclear physics (Akkoyun Bayram, Kara and Sinan, 2013).

Today, discussions about neural networks take place everywhere, their future being closely related to hardware development. Currently, most part of the neural networks development is improving. The companies are working on three types of chips: neuro-digital, analog and optical. However, some companies are performing to create a network application appropriate to a Neural Integrated Circuit. These Neural Integrated Circuits together with the neurons from digital sphere seem to be the forefront in the near future.

Although optical chips look very promising, it seems that it takes some time to be used in commercial applications.

ARTIFICIAL NEURAL NETWORKS STRUCTURE

In order to understand the functioning of an artificial neural network, a preliminary study of the biological neuron is necessary.

Biological Neuron

The biological neuron consists of: *neuronal body* (*soma*), consisting of membrane and intercellular substance, its role being to transform input signals into output signals; *dendritic tree*, representing neuronal extensions of the body, designed to collect incoming signals from other neurons; *axon*, which is a prolongation of the neuronal body and has the role to transfer the output signal to other neurons through axonal arbor.

Figure 1. The biological neuron

Source: Adapted from Stancu, S., ASE, 2012.

Neurons are interconnected through links called synapses, the contact points between dendritic tree limbs of a presynaptic neuron and the axonal arbor limbs of a postsynaptic neuron.

The neuron receives information as an electrical nerve impulse through the dendrites. These impulses cause neural depolarization of the membrane, that is, changes in the potential difference between the outside and the inside of the cell.

The local potentials generated on the membrane surface are summarized and if the potential result exceeds a certain value – called threshold – then a potential action is generated and it is transmitted along the axon through the synaptic connection.

Figure 1 shows the basic structure of a biological neuron.

When the impulses reach the synapsis, they cause the release of the chemical substance that carries the information, named neurotransmitters,

which depends on received impulses and other factors. The post-synaptic membrane receives the neurotransmitters and leads to changes in ionic permeability of the membrane called depolarization. Synapses can be excitatory (if they cause positive depolarization) or inhibitory (if they cause negative depolarization).

Artificial Neuron

In a neural network, the artificial neuron is similar to the biological neuron, called simple neuron. Each neuron has m inputs and one output.

The inputs u_i , where $i = 1, m$. $i = 1, m$ are real numbers and represent signals from other neurons or from the outside world, corresponding to electrical signals from the biological model. A weight is assigned to each input u_i , related to

synaptic value of the biological neuron. The output signal is given by:

$$y = f(< w, u >) = f(w'u) = f\left(\sum_{i=1}^m w_i u_i\right) \quad (1)$$

Where:

$u = (u_1, u_2, \dots, u_m)'$ $u = (u_1, u_2, \dots, u_m)' \in R^m$ - inputs vector ;

$w = (w_1, w_2, \dots, w_m)'$ $u = (u_1, u_2, \dots, u_m)' \in R^m$ - weights vector;

$f(w'u)$ - activation function (or transfer, training, adaptation)

Let z be the variable (merge function) represented by the scalar product:

$$z = < w, u > = w'u = \sum_{i=1}^m w_i u_i \quad (2)$$

As a result, in the simplest case, the output (the activation function) is calculated as

$$y = f(z) = \begin{cases} 1 & \text{if } w'u \geq \tau \\ 0 & \text{otherwise} \end{cases}$$

where τ is the activation threshold.

NEURAL NETWORKS ARCHITECTURE

Neural networks are designed as a black box, that is a device that accepts inputs and produce outputs. Figure 3 shows a typical structure of multi-layer neural network.

The number of input neurons corresponds to the number of input variables of the neural network, as the number of output neurons corresponds to the number of output variables of the network. The number of neurons in the hidden layer depends on the particular application of the network.

INTERNAL AND EXTERNAL NEURAL NETWORKS STRUCTURE

There are two different classification levels of the structure of neural networks. The first level is known as the *external structure*. The term '*external*' describes the layout of inputs, outputs, hidden layers that compose the network and the connections between them.

The second level is the *internal structure*. This is related to the actual connections between individual nodes, both within each layer and between layers.

Figure 2. The anatomy of a neuron with single output
Source: Adapted from Stancu, S., ASE, 2012.

Figure 3. Multilayer ANN architecture

Source: Adapted from Stancu, S., ASE, 2012.

The External Structure of a Neural Network

There are several external structures common to a neural network, namely

- Single input and single output (SISO);
- Multiple input and single output (MISO);
- Multiple input and multiple output (MIMO)

- Single input and multiple output (SIMO).

Figures 4 and 5 show a SISO network with and without threshold.

The next network, classified by complexity is the MISO network. This type of network takes inputs from many variables and uses them to predict the value of a unique output variable.

Figure 6 shows an example of a MISO system.

Figure 4. SISO Network structure with single hidden layer and three nodes, without threshold

Source: Adapted from Stancu, S., ASE, 2012.

Figure 5. SISO Network structure with single hidden layer and three nodes, with threshold
Source: Adapted from Stancu, S., ASE, 2012.

Figure 6. MISO Network structure with single hidden layer and three nodes
Source: Adapted from Stancu, S., ASE, 2012.

The most complex network architecture is the MIMO network. In this network, we will use many variables for input in order to predict values for many output variables. Figure 7 illustrates an example of MIMO network.

MIMO network is very suitable to be used for online applications, as it can predict values for several variables that may be of interest in the process, with only one input pass-through the network.

The Internal Structure of a Neural Network

Individual connections between the nodes show the internal structure of a neural network. We can connect one node to any other node in the networks. Figures 8-10 show three options for connecting nodes to each other. The layers J, K, L may be any layer in the network.

If there is at least one hidden layer, there are two main architectures of an ANN, namely:

Figure 7. MIMO Network structure with 3 input variables, 3 output variables, single hidden layer and 3 nodes

Figure 10. Connection options in a neural network. Recurrent connection
Source: Adapted from Stancu, S., Constantin, A.M., ASE, 2014.

- Feedforward networks (where the propagation arises before the signal)
- Feedback network (where the propagation arises after the signal).

The two types of architecture are shown in Figures 11 and 12.

Multilayer ANN

Multilayer networks are feedforward networks with one or many hidden layers between the input layer and the output layer. Figure 11 shows an example with three hidden layers.

In general, the more complex is the ANN – in terms of layers number and nodes number in a

layer- the higher the computing capabilities are. These multilayered networks have a greater power of representation compared to the single layer ANN, where nonlinearity is introduced through the driving function.

CLASSIFICATION OF THE NEURAL NETWORKS

The main types of neural networks are:

- Neural network with forward signal propagation (e.g. simple perceptron, multilayered perceptron);
- Radial networks;

Figure 11. Feedforward network architecture
Source: Adapted from Stancu, S., ASE, 2012.

Figure 12. Feedback network architecture

Source: Adapted from Stancu, S., ASE, 2012.

Figure 13. ANN feedforward with 3 hidden layers

Source: Adapted from Stancu, S., ASE, 2012.

- Self-organizing networks (e.g. Kohonen network);
- Recurrent networks;
- Stochastic neural networks (e.g. Boltzmann machines);
- Modular neural networks;
- Associative neural networks.

Given the characteristics of a neural network:

- Linear activation functions vs. non-linear activation functions;
- Directly operating mode (feed-forward) vs recurrently operating mode;
- Supervised learning law vs. unsupervised learning law;
- Competing layers vs. passive layers;

we can offer an overview of the achievements in neuronal computation, namely the taxonomy of neural networks.

Without claiming to fully include the existing class of neural networks, the above four features allow to frame most of neural networks.

Any neural network is characterized by three elements: the model of the neuron, network architecture and the training algorithm used.

Among the neural network architectures, feed-forward networks (connections are unidirectional, no feedback loops) were the most studied. In this type of network, neurons are arranged in layers, output neurons of the lower layers being applied to the inputs of neurons in the layer immediately below.

Figure 14. Basic classification of artificial neural networks

Source: Adapted from Stancu, S., ASE, 2012.

The well-known multilayer perceptron has this type of structure, the wide range of applications where it was used being a proof of the capabilities if such a system.

The main quality of neural networks is the ability of classification. The most commonly used neural classifiers are presented in the following taxonomy, depending on the type of input (binary or continuous), on the driving mode, (supervised or unsupervised) and on the network architecture:

The blocks located at the bottom of Figure 15 indicate classical algorithms closest to the appropriate neuronal classifier.

THE USE OF NEURAL NETWORKS IN ECONOMICS

In general, neural networks produce more accurate forecasts than a corresponding linear models. However, neural networks have small disadvantages and therefore they should be considered complementary instruments.

Neural networks have been successfully applied to the macroeconomic variables. Applications in macroeconomics are still developing, standing at the border to empirical economic methods.

ANN has a broad spectrum of use, namely:

- In determining the output as an economic result, both in the case of single-output and in the case of multi-output;
- In forecasting macro or micro indicators, such as: forecasting GDP, inflation, unemployment, exchange rate;
- Symbiosis ANN fuzzy, given the role of fuzzy sets in practice
- Symbiosis ANN- genetic algorithms;
- ANN applications in game theory, in finance etc;
- ANN applications in pattern recognition theory;
- The role of ANN in the complex called Big Data from an economic perspective.

CONCLUSION

During recent years, neural networks began to be studied in all research fields and implemented in many types of expert systems, automatic etc.

The research interests into neural networks has strongly increased as neuronal computation addresses complex issues in an effective and easy

Figure 15. Neural classifiers

Source: Adapted from Stancu, S., ASE, 2012.

method to implement by applying algorithms in automated systems. Moreover, it performs better, with greater accuracy, in extracting and manipulating information in the input data set.

FUTURE RESEARCH DIRECTIONS

Increasing the scope of applying artificial neural networks, their use in all fields will help to streamline decision making, control activity and the activity of micro and macroeconomic modelling.

Currently, the main concern is finding an unique model for the optimization of decisional strategies using neural network in nonlinear modelling. The dependence on a single model for more decision-making strategies can produce significant errors from 10% to 75%, thus it is necessary to build sets of models/strategies in order to form all predictors.

The simplest neural network model is used in the process of validating the transparency of the data which will be entered in predictive-decision process. The other two strategies are designed

to create new disturbed versions of the learning sets, thus all network components will be trained on different data sets. Therefore, an unique set for each component is created by replacing the original data with uniform probability distribution.

Another important issue in forecasting is the accuracy of the neural network ensemble: the three strategies to optimize decisions on applications for scorecards and default prediction.

At the macro-level, the main issue is to find those economic models that aim to formulate and characterize the equilibrium.

KEY TERMS AND DEFINITIONS

Action Potential: The stereotypical voltage spike that constitutes an active output from a neuron. They are propagated along the axon to other neurons.

Arbor: Usually used in the context of a dendritic arbor, the tree-like structure associated with dendritic branching.

Axon: The fibre that emanates from the neuron cell body or soma and that conducts action potentials to other neurons.

Dendrite: One of the branching fibres of a neuron, which convey input information via PSPs.

Feedback Neural Networks: Those networks in which the output neurons can be interconnected with those of the input layer, thereby giving rise to an iterative process.

Feed-Forward Neural Networks (Where the Propagation Arises Before the Signal): Those networks in which the neurons of a layer are interconnected with those of the next layer whereas the neurons of the same later are not connected.

Potential Difference: The voltage difference across the cell membrane.

Presynaptic Membrane: That part of a synapse which is located on the axon terminal.

PSP: Postsynaptic Potential. The change in membrane potential brought about by activity at a synapse.

Receptor Sites: The sites on the postsynaptic membrane to which molecules of neurotransmitter bind. This binding initiates the generation of a PSP.

Recurrent Neural Networks (Feedback): That RNA forward type, where outputs are connected with their inputs.

Soma: The cell body.

Synapse: The site of physical and signal contact between neurons. On receipt of an action potential at the axon terminal of a synapse, neurotransmitter is released into the synaptic cleft and propagates to the postsynaptic membrane. There it undergoes chemical binding with receptors, which, in turn, initiates the production of a postsynaptic potential (PSP).

Optimization of Antenna Arrays and Microwave Filters Using Differential Evolution Algorithms

N

Sotirios K. Goudos

Aristotle University of Thessaloniki, Greece

INTRODUCTION

Several evolutionary algorithms (EAs) have emerged in the past decade that mimic biological entities behavior and evolution. Darwin's theory of evolution is the major inspiration source for EAs. The foundation of Darwin's theory of evolution is natural selection. The study of evolutionary algorithms began in the 1960s. Several researchers independently developed three mainstream evolutionary algorithms, namely, genetic algorithms (Goldberg, 1989), evolutionary programming (Fogel, 1995), and evolution strategies (Beyer & Schwefel, 2002). EAs are widely used for the solution of single and multi-objective optimization problems. Swarm Intelligence (SI) algorithms are also a special type of EAs. SI can be defined as the collective behavior of decentralized and self-organized swarms. SI algorithms among others include Particle Swarm Optimization (PSO) (Kennedy & Eberhart, 1995), Ant Colony Optimization (Dorigo & Stutzle, 2004), and Artificial Bee Colony (ABC) (Karaboga & Basturk, 2007).

An evolutionary algorithm that has recently gained popularity is Differential Evolution (DE) (R. Storn & Price, 1995; R. Storn & Price, 1997). DE is a population-based stochastic global optimization algorithm. DE has been used in several real world engineering problems like fuzzy logic controller design problem (Cheong & Lai, 2007), molecular sequence alignment problem (Kukkonen, Jangam, & Chakraborti, 2007), and automatic image pixel clustering (Das & Konar, 2009). The fact that the DE algorithm can handle efficiently arbitrary optimization problems has made it

DOI: 10.4018/978-1-5225-2255-3.ch572

popular for solving problems in electromagnetics. Therefore, DE has been applied successfully to a variety of constrained or unconstrained design problems in electromagnetics (Goudos, Siakavara, Samaras, Vafiadis, & Sahalos, 2011a; Goudos, Siakavara, Vafiadis, & Sahalos, 2010; Goudos, Zaharis, & Yioultsis, 2010 ; Kurup, Himdi, & Rydberg, 2003).

The purpose of this chapter is to briefly describe the DE algorithm and its variants and present their application to antenna and microwave design problems. This chapter presents results from design cases using self-adaptive DE. The chapter is supported with an adequate number of references. This chapter is subdivided into five sections. The "Background" Section presents the issues, problems and trends with DE for wireless communications. Then we briefly present the different DE algorithms. In the next Section, we describe the design cases and present the numerical results. An outline of future research directions is provided in the following Section while in the "Conclusion" Section we conclude the chapter and discuss the advantages of using a self-adaptive DE-based approach in the design and optimization of microwave systems and antennas. Finally, an "Additional Reading Section" gives a list of readings to provide the interested reader with useful sources in the field.

BACKGROUND

Differential evolution was introduced proposed by Kenneth V. Price and R. Storn in 1995. It uses

real operators for mutation and crossover, instead of the binary operators used in the first GAs. That fact has made DE suitable for solving real-valued problems. DE is a very simple but very powerful stochastic global optimizer. It has been used to solve problems in many scientific and engineering fields and proved to be a very efficient and robust technique for global optimization. In 1997, Storn established a website (Rainer Storn) to where DE source code is publically available for several popular programming languages. Since then there is an explosive growth in differential evolution research.

One of the DE advantages is that very few control parameters have to be adjusted in each algorithm run. However, the control parameters involved in DE are highly dependent on the optimization problem. Therefore, one of the major issues with DE is the correct selection of the control parameters. A basic trend in DE research is the control parameter setting, which has been extensively studied in the literature (Eiben, Hinterding, & Michalewicz, 1999). The effect of the population size was reported in (Feoktistov & Janaqi, 2004).

Another issue is the selection of the appropriate strategy for trial vector generation, which requires additional computational time using a trial-and-error search procedure. Therefore, it is not always an easy task to fine-tune the control parameters and strategy. Since finding the suitable control parameter values and strategy in such a way is often very time-consuming, there has been an increasing trend among researchers in designing new adaptive and self-adaptive DE variants. A DE strategy (jDE) that self-adapts the control parameters has been introduced in (Brest, Greiner, Boskovic, Mernik, & Zumer, 2006). This algorithm has been applied successfully to a microwave absorber design problem (Goudos, 2009) and linear array synthesis (Dib, Goudos, & Muhsen, 2010). SaDE, a DE algorithm that self-adapts both control parameters and strategy based on learning experiences from previous generations is presented in (Qin, Huang, & Suganthan, 2009).

SaDE has been applied to microwave filter design, (Goudos, Zaharis, et al., 2010), and to linear arrays synthesis (Goudos, Siakavara, Samaras, Vafiadis, & Sahalos, 2011b).

Composite DE (CoDE) (Y. Wang, Cai, & Zhang, 2011) is an adaptive DE variant, which combines three different trial vector generation strategies with three preset control parameter settings. The above combination is performed in a random way in order to generate trial vectors. The main advantage of CoDE is that it has a simple structure and thus it is very easy to be implemented in any programming language.

Most of the DE strategies or variants use the binomial crossover operator, which has been found to produce better results than the exponential crossover operator (Mezura-Montes, Velazquez-Reyes, & Coello Coello, 2006). The authors in (Guo & Yang, 2015) propose an alternative crossover operator, namely the eigenvector-based crossover. This operator utilizes the eigenvector information of the covariance matrix of the population to rotate the coordinate system. Additionally, this crossover operator can be applied to any DE variant. In (Goudos, 2015) the eigenvector-based operator is combined with CoDE to introduce a new algorithm the Composite DE with Eigenvector-Based Crossover (CODE-EIG).

The performance comparison of DE among other popular algorithms is another open issue. DE produced better results than PSO on numerical benchmark problems with low and medium dimensionality (30 and 100 dimensions) (Vesterstrom & Thomsen, 2004). However, on noisy test problems, DE was outperformed by PSO. In (Goudos, 2009) a comparative study between DE and PSO variants is presented for the design of radar absorbing materials (RAM). The number of problem dimensions was 10 and DE outperformed the PSO variants in terms of convergence speed and best values found. In (Panduro, Brizuela, Balderas, & Acosta, 2009) a comparison between DE, PSO and Genetic algorithms (GAs) for circular array design is presented. DE and PSO showed similar performances and both of them had better

performance compared to GAs. In (Goudos, et al., 2011a) the jDE outperformed the classical DE and PSO in antenna design problems. However, these results cannot lead to the general conclusion that DE outperforms PSO in all optimization problems in electromagnetics.

We cannot consider the findings about DE-variants obtained from a testbed as being universally applicable. For a specific application, it may be worthwhile to revisit certain variants of DE depending on the properties of the objective functions at hand.

Differential Evolution Algorithm

A population in DE consists of NP vectors $\bar{x}_{G,i}, i = 1, 2, \dots, NP$, where G is the generation number. The population is initialized randomly from a uniform distribution. Each D-dimensional vector represents a possible solution. The initial population evolves in each generation with the use of three operators: mutation, crossover and selection. Depending on the form of these operators several DE variants or strategies exist in the literature (R. Storn, 2008; R. Storn & Price, 1997). The choice of the best DE strategy depends on problem type (Mezura-Montes, et al., 2006). In jDE and SaDE the following four strategies are used for trial vector generation. These include *DE/rand/1bin*, *DE/rand-to-best/2/bin*, *DE/rand/2/bin*, and *DE/current-to-rand/1* (Iorio & Li, 2004). In these strategies a mutant vector $\bar{v}_{G+1,i}$ for each target vector $\bar{x}_{G,i}$ is computed by:

$$\begin{aligned} & \text{DE / rand / 1 / bin} \\ & \bar{v}_{G+1,i} = \bar{x}_{G,r_1} + F(\bar{x}_{G,r_2} - \bar{x}_{G,r_3}), \quad r_1 \neq r_2 \neq r_3 \\ & \text{DE / rand - to - best / 2 / bin} \\ & \bar{v}_{G+1,i} = \bar{x}_{G,i} + F(\bar{x}_{G,best} - \bar{x}_{G,i}) + F(\bar{x}_{G,r_1} - \bar{x}_{G,r_2}) + F(\bar{x}_{G,r_3} - \bar{x}_{G,r_4}), \quad r_1 \neq r_2 \neq r_3 \neq r_4 \\ & \text{DE / rand / 2 / bin} \\ & \bar{v}_{G+1,i} = \bar{x}_{G,r_1} + F(\bar{x}_{G,r_2} - \bar{x}_{G,r_3}) + F(\bar{x}_{G,r_4} - \bar{x}_{G,r_5}), \quad r_1 \neq r_2 \neq r_3 \neq r_4 \neq r_5 \\ & \text{DE / current - to - rand / 1 / bin} \\ & \bar{v}_{G+1,i} = \bar{x}_{G,i} + K(\bar{x}_{G,r_1} - \bar{x}_{G,i}) + F(\bar{x}_{G,r_2} - \bar{x}_{G,r_3}), \quad r_1 \neq r_2 \neq r_3 \end{aligned}$$

where r_1, r_2, r_3, r_4, r_5 are randomly chosen indices from the population, which are different from index i , F is a mutation control parameter, K a

coefficient responsible for the level of recombination that occurs between $\bar{x}_{G,i}$ and $\bar{x}_{G,r_1}$.

After mutation in each generation for every vector of the population, the crossover operator is applied to generate a trial vector $\bar{u}_{G+1,i} = (u_{G+1,1i}, u_{G+1,2i}, \dots, u_{G+1,ji}, \dots, u_{G+1,Di})$ whose coordinates are given by:

$$u_{G+1,ji} = \begin{cases} v_{G+1,ji}, & \text{if } rand_{j[0,1]} \leq CR \text{ or } j=rn(i) \\ x_{G+1,ji}, & \text{if } rand_{j[0,1]} > CR \text{ and } j \neq rn(i) \end{cases}$$

where $j = 1, 2, \dots, D$, $rand_{j[0,1]}$ is a number from a uniform random distribution within the interval $[0,1)$, $rn(i)$ a randomly chosen index from $(1, 2, \dots, D)$, and CR the crossover constant from the interval $[0,1]$. DE uses a greedy selection operator, which for minimization problems is defined by:

$$\bar{x}_{G+1,i} = \begin{cases} \bar{u}_{G+1,i}, & \text{if } f(\bar{u}_{G+1,i}) < f(\bar{x}_{G,i}) \\ \bar{x}_{G,i}, & \text{otherwise} \end{cases}$$

where $f(\bar{u}_{G+1,i})$, $f(\bar{x}_{G,i})$ are the fitness values of the trial and the old vector respectively. Therefore, the newly found trial vector $\bar{u}_{G+1,i}$ replaces the old vector $\bar{x}_{G,i}$ only when it produces a lower objective-function value than the old one. Otherwise, the old vector remains in the next generation. The stopping criterion for the DE is usually the generation number or the number of objective-function evaluations.

jDE

Storn has suggested (R. Storn & Price, 1997) that the differential evolution control parameters are adjusted in the following way: $F \in [0.5, 1]$, $CR \in [0.8, 1]$ and $NP = 10D$. In (Brest, Boskovic, Greiner, Zumer, & Maucec, 2007), a novel approach is proposed for the self-adapting

of DE control parameters. This strategy is based on *DE/rand/1/bin* scheme. Each vector is extended with its own F and CR values. The control parameters are self-adjusted in every generation for each individual. Therefore, by using the self-adaptive algorithm the user does not have to adjust the F and CR parameters while the time complexity does not increase. More details about the jDE algorithm can be found in (Brest, et al., 2007; Goudos, et al., 2011a).

DE with Strategy Adaptation (SaDE)

In the SaDE (Qin, et al., 2009) algorithm both the trial vector generation strategies and the control parameters are self-adapted according to previous learning experiences. SaDE maintains a strategy candidate pool, consisting of four commonly used strategies. Each strategy is assigned a certain probability. The sum of all probabilities is equal to one. These probabilities are initialized with a value of 0.25 and gradually adapted during evolution. An additional parameter called the learning period (LP) is introduced in (Qin, et al., 2009). This corresponds to the number of the previous generations that store the success and fail statistics. After LP generations, the probabilities of selecting different strategies are updated. Therefore, the strategies with high success rates have higher probability to be applied at the current generation. More details about the SaDE algorithm can be found in (Qin, et al., 2009).

APPLICATIONS, RESULTS, AND DISCUSSION

In this Section, we provide representative microwave and antenna design problems that are solved with the above-mentioned algorithms. First, we present an example case linear array synthesis. The design method is JDE. In the second example, we address the problem of sparse array synthesis using the SADE algorithm. The third example uses the jDE algorithm for the design of a bandpass

microwave filter under constraints for wireless communications.

Linear Array Synthesis Using jDE

Several applications of modern wireless communications systems require radiation characteristics such as higher directivity that cannot be achieved by using a single antenna. The use of antenna arrays is the obvious solution for such a case. Among others, antenna arrays are employed for several radar and wireless communications applications in space and on earth. Their advantages include the possibility of fast scanning and precise control of the radiation pattern.

Synthesis of linear antenna arrays has been extensively studied in the last decades using several analytical or stochastic methods. The linear array design problem is multimodal and therefore requires the use of an optimization method that does not easily get trapped in local minima. Common optimization goals in array synthesis are the sidelobe level suppression (while preserving the main lobe gain) and the null control to reduce interference effects. For a uniformly excited linear array, the above goals can be achieved by finding the optimum element positions and phases. We assume a $2N$ -element linear array, which is symmetrically placed along the x -axis, see Figure 1.

We examine the case of position-phase synthesis for a 32-element array. For this case, the total number of unknowns is $2N$. We assume that $d_{\min} = 0.5\lambda$, and $d_{\max} = \lambda$ as in (Kurup, et al., 2003), where $d_{\min}, d_{\max}$ is the minimum and

jDE	-23.59	-22.78	-23.24	0.278

maximum distance between two adjacent elements respectively.

Table 1 presents the statistical results of the objective-function values for this case. The jDE algorithm clearly outperforms the classical DE. Figure 2 shows the convergence-rate plots. DE and jDE converge at similar speeds.

Figure 3 presents the pattern of the best design obtained. The maximum SLL value is -23.59dB (instead of -23.34dB in (Kurup, et al., 2003)).

Sparse Array Synthesis Using the SADE Algorithm

The second example addresses also the array design problem using a different approach. The use of a uniformly excited array has the advantage of reduced cost and complexity regarding feeding

network design. In such a case, sidelobe level suppression can be achieved by finding the optimum element positions. The constraints that the element positions must satisfy increase the difficulty of the design problem. These could include the minimum and maximum distance between two adjacent elements, the total array length, the sidelobe level suppression in specified angular intervals, and the mainlobe beamwidth set within predefined limits. SaDE and the common DE/rand/1/bin strategy are applied to a 37-element array design cases. The algorithms are run for 100 independent trials. In order to compare results with [15] the number of objective-function evaluations is set to 60,000. Therefore, the population size is set equal to 50 and the number of iterations to 1200. The total array length is set to 21.996λ . The comparative results are presented in Table 2. Although both DE algorithms obtain the same best value, the standard deviation value is smaller for SaDE. The results indicate that the DE algorithms outperform again the real GA. Figure 4 shows the convergence rate graph. It seems that DE and SADE converge at similar speeds. Figure 5 presents the pattern of the best design obtained by the DE algorithms.

Microstrip Bandpass Filter Design Using jDE

Microwave filters are among the important components of a modern wireless communication system. Several papers exist in the literature that address the filter design problem (X. H. Wang, Wang, & Chen, 2008).

The final example presents the design of a bandpass microstrip filter. We consider a substrate with dielectric constant equal to 9 and 0.66mm thickness (Hennings, Semouchkina, Baker, & Semouchkin, 2006). Such a filter design problem can be defined by two objectives subject to two constraint functions. The first objective is to maximize the $|S_{21}|$ in the passband frequency range. The second objective is to minimize the $|S_{21}|$ in the stopband frequency range. Additionally, constraints can be set for $|S_{21}|$ levels in both

the passband and the stopband. These are set to a level below -20dB in the stopbands and to a level above -3dB in the passband. The bandpass filter is designed for operation between 4.8GHz and 5GHz where is the passband. The two stopbands are defined from 4.3GHz to 4.6GHz and from 5.2GHz to 5.5GHz. The geometry of the bandpass filter is shown in Figure 6. The design parameters of the filter are 6.

Using a trial and error search we have found that 15 vectors is an adequate population size for that design problems. The total number of generations is set to 100. The best results after 10 independent trials are selected. For each run, 17 frequency sweeps are taken in the frequency range 4.3-5.5 GHz. The results for both (DE and jDE) algorithms are shown in Table 3. It is evident that the jDE outperforms the DE algorithm. Figure 7 presents the convergence rate. The DE strategies seem to converge at similar speeds.

Figure 8 shows the simulated frequency response of bandpass filter best obtained design.

FUTURE RESEARCH DIRECTIONS

The research domain of evolutionary algorithms is growing rapidly. A current and growing research trend in evolutionary algorithms is their hybridiza-

Figure 4. Convergence rate for the 37-element sparse array

tion with local optimizers. These algorithms are called Memetic Algorithms (MAs). MAs can be highly efficient due to this combination of global exploration and local exploitation.

The combination of DE algorithms with the eigenvector-based crossover operator is another research option. One example is the CODE-EIG, which extends the Composite DE with the eigenvector-based crossover operator. The CODE-EIG algorithm is a powerful and robust global optimizer, which selects the appropriate strategy for trial vector generation and control parameters from a predefined candidate pool. An additional control parameter that is included in CODE-EIG is the eigenvector ratio. Thus, CODE-EIG requires only the adjustment of three parameters: the population size, the number of iterations and the eigenvector ratio. Possible modifications of the CODE-EIG algorithm could be another field of study.

The application of multi-objective DE algorithms to antenna and microwave design problems introduces new challenges regarding performance and computational cost. Recently a novel Memetic Multi-objective DE algorithm has been applied to subarray design (Goudos, Gotsis, Siakavara, Vafiadis, & Sahalos, 2013). This new multi-objective DE version uses the Random Walk algorithm for local optimizer in order to search around small regions in the parameter space. Therefore, new research directions have to be explored.

CONCLUSION

In this chapter, we discussed and evaluated the application of self-adaptive DE optimizers to antenna and microwave design problems. We have presented common and state-of-the-art DE strategies found in the literature. These were the jDE and the SaDE algorithms. The DE algorithms are generally robust optimizers. In classical DE algorithms, the selection of the appropriate strategy for trial vector generation and control parameters requires additional computational time using a trial-and-error search procedure. Therefore, it is not always an easy task to fine-tune the control

Figure 7. Convergence rate for the microstrip bandpass filter design case

Figure 8. Simulated frequency response of the best filter obtained by jDE

parameters and strategy given also that commonly the appropriate control parameters and strategy selection are problem dependent. The SaDE and jDE advantage though, is the fact that no additional time for solving a given problem is required. SaDE and jDE require only the adjustment of two parameters: the population size and the number of iterations.

The jDE algorithm has been applied to the design of an E-shaped patch antenna and a 60-element array. In both cases the results were compared with the *DE/rand/1/bin* strategy. Compared with the classical DE strategy the jDE strategy converges faster and obtains better results.

We have also presented the design case of a tri-band microwave filter for WiFi and WiMax. The optimizer used was SaDE. The filter found exhibits low loss in the passbands and high isolation between the passbands. The proposed synthesis procedure can be used to any filter design problem that requires optimization of the geometry parameters. The correct selection of the objective function is essential for the efficient application of the SaDE algorithm.

Recent self-adaptive DE algorithms and their application to electromagnetic design will be part of our future work. DE-based optimizers can be used in cases where the computational time plays an important role. The DE algorithms combined with a numerical method can be valuable tools for constrained single or multi-objective optimization problems in wireless communications.

KEY TERMS AND DEFINITIONS

Genetic Algorithms: A stochastic population-based global optimization technique that mimics the process of natural evolution.

Sidelobe Level (SLL): The ratio, usually expressed in decibels (dB), of the amplitude at the peak of the main lobe to the amplitude at the peak of a side lobe.

WiMAX: A wireless communications standard designed to provide 30 to 40 megabit-per-second data rates.

Wireless Local Area Network (WLAN): A network in which a mobile user can connect to a local area network (LAN) through a wireless (radio) connection.

QoS Architectures for the IP Network

N

Harry G. Perros

North Carolina State University, USA

INTRODUCTION

When we call someone over the Internet using a service such as Skype or Google talk, we may experience certain undesirable problems. For instance, we may not be able to hear the other person very well, or even worse, the call may be dropped. This is in contrast to using the regular telephone system where the quality of the voice is always very good. Similarly, during a conversational video call, the picture may freeze, or there may be pixilation, or the call may be dropped. The reason for these problems is that the IP packets that carry the contents of our call are not delivered on time at the destination so that they can be played out at the right time. Also, some of the packets may be lost while they are traversing the Internet. In order to eliminate these problems, the underlying IP network has to be able to provide Quality of Service (QoS) guarantees. Several schemes have been developed that enable the IP network to provide such guarantees. Of these schemes, the Multi-Protocol Label Switching (MPLS) and the Differentiated Services (DiffServ) are the most widely used. In this article, some of the salient features of MPLS and DiffServ are reviewed.

BACKGROUND

QoS is a well-understood and studied topic within the networking community. It is typically expressed in term of the following three metrics: the end-to-end delay, the jitter, and the packet loss rate. The end-to-end delay is the amount of time it takes to transfer a packet from the transmitter to the receiver, and it consists of a) the end-to-end propagation delay, b) delays induced by transmission systems and processing times inside the routers, and c) delays a packet encounters due to queueing in the buffers of the routers. Jitter refers to the variability of the inter-arrival times of the packets at the destination, and the packet loss rate is the percent of packets that are lost.

Different applications have different tolerance to these QoS metrics. Table 1 relates various common networking applications to the end-to-end delay and packet loss rate. For instance, for conversational voice and video it is important that packets should be delivered to the destination in less than 150 msec in order to maintain user satisfaction. (Studies have showed that in fact an end-to-end delay of up to 220 msec can be tolerated.) On the other hand, a packet loss rate of about

Table 1. QoS metrics for common networking services

Tolerance for packet loss	<i>Tolerant</i>	Conversational voice and video	Voicemail	Streaming audio and video	Fax
	<i>Intolerant</i>	Remote app., command and control games	e-commerce web browsing	Texting, file transfer (foreground)	File transfer (background), email
		<i>Interactive delay</i> < 1 s	<i>Responsive delay</i> ~ 1 s	<i>Timely delay</i> ~ 10 s	<i>Background delay</i> >> 10 s
		Tolerance for delay			

DOI: 10.4018/978-1-5225-2255-3.ch573

1 in 100 can be tolerated. That is, conversational voice and video type of applications are packet-loss tolerant but they have a strict end-to-end delay constraint, i.e. they are delay intolerant. On the other hand, a file transfer service is delay tolerant but packet-loss intolerant. This is because we do not expect a file to be delivered immediately, but the integrity of the file is important, and any lost packets have to be re-transmitted.

In view of the above, the question that arises is how can the network provide different QoS to different applications. In order to answer this question, let us first take a look at how the IP network routes packets. Each IP packet consists of a header and a payload, and the header contains different fields one of which is the destination IP address. When a packet arrives at an IP router, the header is examined and the destination address is used in a forwarding routing table in order to find out the next IP router to which the IP packet should be sent. This forwarding operation is carried out at each router along the path followed by the packet, until the packet reaches its destination. The forwarding routing table in each IP router is constructed using a routing protocol, such as the Open Shortest Path First (OSPF). The path that a packet follows is the shortest path in terms of the number of hops, i.e., routers. The advantage of this type of routing is that it is simple. However, since it minimizes the number of hops, it is difficult to guarantee any QoS metrics, such as end-to-end delay, jitter, and packet loss rate. For instance, the fact that the path that a packet follows has the smallest number of hops, does not necessarily mean that it has the shortest end-to-end delay. On the other hand, if all routers have approximately the same packet loss rate, then the shortest path will result to the lowest end-to-end packet loss rate.

Another problem is that a router cannot distinguish packets without an additional mechanism, such as, packet inspection or packet classification. Therefore, it cannot give packets from delay-intolerant applications a higher priority for transmission out of an output port over packets from delay-tolerant applications. (This is necessary, if we want to minimize the end-to-end delay of packets from

a delay-intolerant application.) In view of this, the only way that delay sensitive applications can be served satisfactorily is to under-utilize the entire network so that the queues of packets waiting for transmission in the output ports of the routers are never too long, and as a result, the delay to transmit a packet out of an output port is negligible. This is known as *over-engineering* the network. This solution is expensive since the links are under-utilized, and also it does not prevent the occurrence of transient traffic congestion. An advantage of over-engineering the network, is that when a link failure occurs, traffic can be redirected over other links without saturating them.

In order to provide QoS guarantees in an IP network without having to operate it at very low utilization, we need a scheme that can carry out *call admission control* and *packet classification*:

- **Call Admission Control:** Before a user or an application starts transmitting packets over the network, we have to make sure that the network has the necessary bandwidth to carry the new flow of packets that will be generated at the expected QoS, without affecting the QoS of the flows of packets that are currently being transmitted over the network. This procedure is known as call admission control;
- **Packet Classification:** Packets should be classified to different classes of service with different priorities, so that they are transmitted out of the output port of a router according to the priority of their class of service.

Several schemes have been developed that enable the IP network to provide QoS guarantees. Of these schemes, the Multi-Protocol Label Switching (MPLS), see IETF RFC 3031 (2001), and the Differentiated Services (DiffServ), see IETF RFC 2474 (1998), are the most widely used. Below, some of the salient features of MPLS and DiffServ are reviewed. For further details the reader is referred to Perros (2014).

Figure 1. The MPLS header

THE MULTI-PROTOCOL LABEL SWITCHING (MPLS) ARCHITECTURE

MPLS was introduced around 2000, and it is currently used extensively in IP networks to provide QoS guarantees for real-time multimedia services, such as voice and video calls, and also to interconnect clouds. MPLS is an architecture that turns the IP network into a *connection-oriented* network. In such a network, the transmission of packets between two users is done over a connection that is established prior to the transmission. This is not a logical connection, such as those established at the TCP level. Rather, a path between the two users is first calculated through the IP network, and then each router along the path reserves bandwidth for this connection on its outgoing link to the next router on the path. It also generates and stores state information regarding the connection. After the connection has been setup end-to-end, the transmission of packets can start. All the packets related to a connection follow the same path through the IP network and they arrive at the destination in the order in which they were transmitted. When the transmission of the packets is completed, the connection is torn down and the bandwidth reserved on each link for the connection is freed. Such a connection is also known as a *virtual circuit*.

In MPLS, a connection is identified by a number that is referred to as the *label*. In IPv4, the label is encapsulated in a header that is inserted between the LLC and the IP headers, as shown in Figure 1. This header is referred to as the MPLS header.

The first field of the MPLS header is a 20-bit field that carries the label. The second field, still known as the experimental field, is a 3-bit field that is used to carry a Class-of-Service (CoS) indication. Multiple MPLS headers can be stacked in an IP packet, and for this the S field is used to indicate the end of the stack. Finally, the Time-to-Live (TTL) field contains the TTL value copied from the IP TTL field at the time the MPLS header is created after it is decremented by 1.

Each router maintains a table of labels and other relevant information for all active connections. When an IP packet arrives at the router, the label carried in the MPLS header is looked up in the table of labels to determine the next router. The IP packet is then switched to the output port of the router that connects to the next destination. In addition, the IP packets of a connection are associated with a QoS class. In MPLS, there are several different QoS classes, and each class has its own scheduling priority for transmission out of an output port of a router. The QoS class of a packet is stored in the table of labels together with the packet's label at the time the connection is setup or it may be carried in the CoS field of the MPLS header. Such a classification scheme allows packets from a delay-sensitive application to be given higher priority for transmission over packets belonging to a delay-insensitive application.

In MPLS, a connection is known as a Label Switched Path (LSP) and an MPLS-enabled router is referred to as a Label Switching Router (LSR). An example of an MPLS connection is shown in Figure 2. Each connection is associated with an

Figure 2. An example of a connection

ingress LSR and an egress LSR. For instance in Figure 2, LSR A is the ingress LSR and LSR J is the egress LSR.

As mentioned above, a connection is identified by a number which is referred to as a label. Whereas it is possible to identify a connection end-to-end by a single label, the normal practice is to identify a connection by a series of labels, with each label being valid only on a single hop. As we can see in Figure 2, the connection is routed through LSRs C, D, and G, and the labels associated with this connection are: 32, 54, 66, and 70. These labels are allocated at connection setup time. Table 2 gives the labels allocated for the connection. (For presentation purposes all the entries are listed together in a single table, although each entry belongs to a different label table. That is, the first entry belongs to the table of labels of LSR A, and so on.). Packets sent to LSR A from user 1 do not normally contain an MPLS header. The MPLS header with the label 32 is added by LSR A. It is then sent to LSR C, where the incoming label is looked up in the table of labels to find the new label and the output port number. The MPLS header is updated with the new label and the IP packet is switched to that particular output port through the switch fabric of the LSR, and eventually it is transmitted out to LSR D. The same action takes place at LSR D. Finally, when it gets to LSR J, its MPLS header is removed and the packet is sent to user 2. We note that the IP packets in the MPLS network are routed using their incoming label and not the destination IP address.

In MPLS the establishment of a connection is done using the RSVP-TE signaling protocol. Call admission control is carried out during the time the connection is setup. Specifically, a router is aware of all the connections that pass through its switch fabric, and therefore, it can decide whether to accept a new connection or not based on the amount of traffic that will be transmitted and the requested QoS. The router stops accepting new connections when it runs out of bandwidth.

The path through the IP network is computed by means separate from the MPLS architecture and it can be the same path as the one calculated using OSPF, referred to as the hop-by-hop path. It may also be a path that satisfies a QoS criterion, such as, minimization of the end-to-end delay, maximization of throughput, etc. Such a QoS criterion may not necessarily be satisfied by the hop-by-hop route, which typically minimizes the number of hops. A path that satisfies a QoS criterion is known as an *explicit route*. Explicit routing can be also used to provide load-balancing in a network, by forcing some of the traffic to

Table 2. Label entries

LSR	Incoming Label	Outgoing Label	Outgoing Port
A	-	32	to LSR C
C	32	54	to LSR D
D	54	66	to LSR G
G	66	70	to LSR J
J	70	-	to user 2

follow different paths through a network, so that the utilization of the network links is as even as possible.

THE DIFFERENTIATED SERVICE (DIFFSERV) ARCHITECTURE

DiffServ predates MPLS by a couple of years. It is widely used by network providers and also in enterprise networks, i.e., privately owned and operated networks, to provide different service to different classes of traffic. Unlike MPLS, it is not a connection-oriented architecture, and call admission control is not done on a per connection basis.

Customers of a network provider are not individual users, but rather companies and other organizations acting on behalf of their members. A customer enters into a Service Level Agreement (SLA) with a network provider, which is basically a contract that spells out how much traffic per class the customer will submit, the customer's expected QoS, and the price for the service. Call admission control is done at the aggregate level, whereby the operator has to figure out whether it can serve a new customer according to the requested SLA without affecting the SLA agreements of the existing customers.

DiffServ operates on the principle of packet classification, whereby each packet in a DiffServ-enabled IP network is classified into a traffic class. Packet classification (or marking) is done at the ingress node using different parameters, such as, source address, destination address, and port numbers. A DiffServ-enabled network may also accept traffic already marked by a user. A DiffServ class is indicated by a number known as the DiffServ Code Point (DSCP). The DSCP is stored in the 8-bit DS field in the IP header. In IPv4, this field is carried in the type of service field, and in IPv6 it is carried in the traffic class field.

Marked packets are treated differently within a DiffServ-enabled router. Typically, the queueing encountered in a router is at the output ports. In DiffServ, multiple queues are maintained at each

output port, one for each DSCP, and a packet waiting to be transmitted out joins the queue associated with its own DSCP. The queues are served according to a scheduler that guarantees that packets in higher-priority queues are transmitted out first. In addition, packets can get dropped when congestion occurs, and dropping priorities are also associated with some of the DiffServ classes of traffic. The set of controls, i.e., queue selection at an output port, scheduling priority for transmission out of the router, and packet dropping priority, is known in the DiffServ architecture as the Per-Hop Behavior (PHB).

In addition to marking and PHB, DiffServ polices the traffic submitted by the users at the ingress routers, the entry points of a DiffServ-enabled IP network. This done to make sure that the customer does not submit more traffic than agreed upon in the SLA agreement. Excess traffic may be dropped, or it may be marked as eligible to be dropped and let into the network. If congestion occurs in a router then the marked packets are dropped first.

The following four DiffServ classes have been defined:

- Expedited Forwarding (EF);
- Assured Forwarding (AF);
- Default class;
- Class Selector (CS).

The Expedited Forwarding (EF) class is used to support applications that require low delay, low jitter, low packet loss, and assured bandwidth, such as VoIP. The Assured Forwarding (AF) class was designed to support data applications with assured bandwidth requirements. That is, packets will be forwarded with a high probability as long as the class rate submitted by the user does not exceed a predefined contracted rate. Twelve different sub-classes, each with a different DSCP, have been defined within the AF class, designated as AF_xy, where x=1,2,3,4 and y=1,2,3. The scheduling priority is determined by the value of x (with 4 being the highest priority) and the dropping

priority by the value of y (with 1 being the lowest priority). The Class Selector (CS) class, is used to represent the group of 8 classes that existed prior to the introduction of DiffServ. They are designated as CS x , where $x=0,1,\dots,7$. CS0 is used to implement the default class, which is the best effort class. Because of its high use, a fair amount of bandwidth needs to be allocated to it.

An example of how different networking applications can be mapped to DiffServ classes is given in Table 3, see Cisco for further details. The meaning of most of these applications is self-evident. The locally-defined mission-critical data class is used to provide an organization with a premium class of service for a select subset of their applications that have the highest business priority for them. For example, an enterprise may have provisioned Oracle, SAP, BEA, and DLSw+, in the transactional data class. However, the majority of their revenue may come from SAP, and therefore they may want to give this application an even higher level of preference by assigning it to a dedicated class such as the locally-defined mission-critical data class. The transactional data class is a combination of transactional client-server applications and interactive messaging applications. The bulk data class is intended for applications that are relatively non-interactive, insensitive

to packet loss, and they typically span their operation over a long period of time as background occurrences. Such applications include: file transfer, e-mail, backup operations, database synchronizing or replicating operations, content distribution, and any other type of background operations. Finally, the scavenger class has a lower priority than the best effort service. Applications assigned to this class are typically entertainment-oriented. These include: peer-to-peer media-sharing applications, such as, KaZaa, Morpheus, Grokster, Napster, and iMesh, gaming applications, such as, Doom, Quake, and Unreal Tournament, and entertainment video applications.

DIFFSERV WITH MPLS

MPLS provides the capability to set up a connection using either the OSPF next hop routing (hop-by-hop route) or an explicit route that optimizes a QoS metric. Explicit routes are calculated by some means outside MPLS. Bandwidth is allocated on each router along the path of the connection, and different QoS classes of traffic can be defined. It is assumed that a policer is set up at the ingress of the MPLS domain to assure that the traffic is conformant, and a scheduler in each router makes sure that packets are transmitted out according to their priority and requested QoS. MPLS does not define QoS classes, nor does it define the policer and the scheduler. On the other hand, a scheduler along with traffic classification and policing are already available through the DiffServ architecture. Consequently, DiffServ and MPLS have been used together in order to provide a single QoS scheme, see IETF RFC 3270 (2002).

FUTURE RESEARCH DIRECTIONS

The MPLS and DiffServ architecture are mature networking solutions that have been in place for well over a decade. These architectures are used within the domain of an operator, and they do

Table 3. Mapping of applications to DiffServ classes

Application	DiffServ Class

Voice	EF
Interactive video	AF41
Streaming video	CS4
Locally defined mission-critical data	AF31
Call signaling	AF31/CS3
Transactional data	AF21
Network management	CS2
Bulk data	AF11
Best effort	CS0
Scavenger	CS1

not provide a solution to the problem of how to guarantee end-to-end QoS over multiple domains.

The issue of multi-domain routing subject to end-to-end QoS constraints was addressed in IETF RFC 4655 (2006), where an entity referred to as the Path Computational Element (PCE) was introduced. This entity is responsible for route selection, admission control, and resource reservation within a domain. A PCE interacts with the PCEs of other domains in order to setup a multi-domain route with end-to-end QoS measures. In Geleji and Perros (2011) several algorithms were studied that permit a PCE of a domain to setup a path across multiple domains under end-to-end QoS constraints.

Quite independently to the PCE effort, there has been a new trend to centralize the management of routers and Ethernet switches. This trend comes under the name of Software-Defined Networks (SDN), with OpenFlow being a well-known SDN protocol, see OpenFlow (2011). Currently, SDN solutions work only within a single domain, but there is a strong effort to expand SDN to guarantee QoS over multiple domains, in which case the PCE solution can be easily incorporated.

Finally, the recent trend of Network-Function Virtualization (NFV), ETSI GS NFV 002 (2013), is likely to revolutionize the way networks devices and services are implemented. This initiative aims at implementing networking device types, currently running on proprietary dedicated hardware, in software that runs in virtual machines in a data center. How the end-to-end QoS will be guaranteed in a virtualized environment is an open issue.

CONCLUSION

In our daily life we use regularly various multimedia services, such as, voice and video calling (Skype, Facetime, Hangouts), video conferencing (WebEx, Telepresence), TV delivered over the Internet (IPTV), video on demand (YouTube, Netflix, Amazon, Google movies) and instant mes-

saging (texting). We also use other apps that often include some of the above multimedia services, such as, online games and assisted living. The QoS of a voice/video call transported over the IP network is critical to the operators and it can be guaranteed by using appropriate QoS schemes in the IP network, such as MPLS with DiffServ. It is expected that the advent of SDN will facilitate the provision of the necessary QoS for critical multimedia services.

KEY TERMS AND DEFINITIONS

Call Admission Control: This is a scheme that assures that there is sufficient bandwidth in the network for a new flow of packets.

DiffServ: A mechanism used in the IP network to provide QoS guarantees on aggregates of flows.

Enterprise Network: A privately owned and operated network.

Explicit Route: A route through the IP network that satisfies a QoS criterion, such as, minimizations of the end-to-end delay, maximization of throughput, etc.

MPLS: A mechanism used in the IP network to provide QoS guarantees. IP packets are forwarded from one network node to the next based on labels rather than IP address.

Network-Function Virtualization (NFV): It is a concept that uses the technologies of IT virtualization in order to virtualize networking functions that may be connected together to create communication services.

Open Shortest Path First (OSPF): A protocol used to construct routes through the IP network that typically minimizes the number of hops (routers).

Propagation Delay: This the time it takes for a bit of data to travel across the network from one node or endpoint to another.

Quality of Service (QoS): It describes how well a flow of packets is served by the network. It is typically measured by different metrics, such as, end-to-end delay, jitter, packet loss rate, network availability, and bandwidth.

RSVP-TE: A signaling protocol for setting connections in an MPLS network.

Service Level Agreement (SLA): A contract between a network provider and a customer that spells out that spells out how much traffic per class the customer will submit, the customer's expected QoS, and the price for the service.

Software Defined Networks (SDN): A centralized solution for managing routers and Ethernet switches.

Voice Over IP (VoIP): A telephone service implemented over the Internet. Voice is packetized into IP packets which are transmitted to the destination over the Internet. At the destination, the voice data is recovered from the packets and played back.

Throughput Dependence on SNR in IEEE802.11 WLAN Systems

Ikponmwosa Oghogho

Delta State University, Abraka-Oleh Campus, Nigeria

INTRODUCTION

The widespread growth and popularity of the internet and wireless devices have placed greater demand on the need for wireless local area networks (WLANs) (Motchanov, 2010). WLANs are presently being used to enable many users share available network resources in a fast and convenient way (Obaidat et al., 2008).

WLANs popularity began when the United States Federal Communications Commission (FCC) opened up the Industrial Scientific and Medical Band (ISM) to the public (Obaidat et al., 2008). Several companies developed wireless solutions during this period but these solutions did not interoperate among themselves.

The IEEE802.11 WLAN working group addressed this issue by developing different IEEE802.11 WLAN standards which can be followed by different vendors. They defined the physical layer to specify multiple communication data rates to be selected for transmission depending on the quality of the current link (SNR observed) (Metreud, 2006).

The degree of performance enjoyed by WLAN users depend largely on the network design. Throughput is an important network parameters identified to be directly influenced by the SNR received by the end users (Metreud, 2006). Throughput depends on the selected communication data rate which is also directly dependent on the SNR observed.

This chapter presents a background study on 802.11 WLANs, their network performance metrics (throughput, SNR, Received Signal Strength Indication, etc.), interactions between TCP

throughput, losses, link adaptation and SNR in WLANs. Cross layer modelling principles and research that models throughput based on SNR only are also presented. Throughput which is largely dependent on the observed SNR is identified in this chapter as a major metric for characterizing IEEE802.11 WLANs.

BACKGROUND OF STUDY

IEEE 802.11 WLANs

The first IEEE802.11 WLAN standard which supported data rates up to 2 Mbps was released in 1997 (Obaidat et al, 2008). The standard defined both the physical layer and the medium access control (MAC) layer. Other IEEE802.11 standards such as IEEE802.11a, IEEE802.11b, IEEE802.11g, IEEE802.11n, (with higher data rates), IEEE802.11e (for better quality of service support) and IEEE802.11i (for security), IEEE802.11ac, IEEE802.11ax have been developed since then.

At the physical layer IEEE 802.11n can provide data rates up to 54Mbps in a 20MHz band with at least 100Mbps at the MAC data services access point using only mandatory features specified in the standard (Metreud, 2006). Newer standards such as IEEE802.11ac and IEEE802.11ax offer up to 1,300Mbps and 2Gbps respectively (Jamie, 2015). The popularity of the IEEE802.11 “family of standards” has continued to increase due to their convenience and the reduction in prices of their hardware. The discussion in this chapter is however limited to the base standards because

available in literature are throughput models which predict throughput directly from observed SNR only for these base standards.

Radio frequency (RF) based WLANs (which are more common than the IR-based ones) operate in the International Scientific and Medical (ISM) band which does not require any licensing from the US FCC (Obaidat et al., 2008). They use RF signals which can pass through obstacles to transmit and receive data through the air without any connecting cables thus providing freedom and flexibility unmatched by Wired LAN.

OSI Model and the IEEE802.11 Physical Layer

Open System Interconnect (OSI) was created by the International standards organization to provide a design standard and reference model to explain how different networking technologies work together and interact (Rachelle, 2001). Network protocols do not necessarily have to follow the OSI model. Seven layers are specified by the model, namely: physical, data link, network, transport, session, presentation and application layers as shown in Table 1. Table 1 also shows the TCP/IP model layers.

Each layer in the OSI model is responsible for specific functions. All layers in the model interact correctly to move data through the network. Understanding and Implementation of networks would be tedious without the OSI model because

it allows networks to be broken up into small pieces that can be easily managed. It also provides a general language which explains components and their functions.

Specifications of connector and interfaces and the cable requirements or medium are defined by the OSI model physical layer. The physical layer handles all aspects of physically moving data from one node to the other and ensures data conversion from the upper layers into 1s and 0s before they are transmitted over the media.

The IEEE802.11 standard defines two physical layer methods: (i) the frequency hopping spread spectrum and (ii) the direct sequence spread spectrum. The base IEEE802.11 DSSS physical layer supports two rates: 1Mbps and 2Mbps. Subsequent IEEE 802.11 standards support higher rates (5.5Mbps, 11Mbps, 54Mbps, 100Mbps, 1,300Mbps, 2Gbps, etc.). Table 2 shows a summary of the different Physical layer alternatives of some IEEE802.11 standard.

Performance Comparison of some IEEE802.11 WLAN Products

Table 3 shows the performance comparison of Wireless LAN products on the market published by Khanduri and Rattan (2013).

Although IEEE802.11g and IEEE802.11n allow higher data rates, the presence of an IEEE802.11b device in the network forces them to function at lower rates (Sarkar and Sowerby, 2009).

Table 1. Description of layers in the OSI model

Layer	OSI Model Layers	TCP/IP Layer	Information or Message Type	
7	Application	Process layer	Data	Mostly software
6	Presentation		Data	
5	Session	Host to host layer	Data	
4	Transport		Segment	
3	Network	Internet layer	Packet	Mostly hardware
2	Data Link	Network Access layer	Frame	
1	Physical		Bit	

(Paul, 2006; Rachelle, 2001)

Table 2. Different physical layer alternatives of some IEEE802.11 standard

Standard	Spectrum: United States (GHz)	Data Rates (Mbps)	Modulation Scheme
Base IEEE802.11	2.402-2.479	1, 2	GFSK, FHSS
	2.402-2.479	1, 2	B/QPSK, DSSS
	850-950 nm	1, 2	PPM, IR
IEEE802.11a	5.150-5.250, 5250-5350, 5725-5825	6-54	OFDM
IEEE802.11b	2.402-2.479	1, 2, 5.5, 11	CCK
IEEE802.11g	2.402-2.479	1-54	OFDM and CCK
IEEE802.11n	2.4 and 5.0	> 100	MIMO and OFDM

(Poole, 2012)

Table 3. Comparison of some wireless products on the market

Product	Compatible With	Major Disadvantages	Major Advantages
802.11a	None	Smallest range of all 802.11 standards	High bit rate in less crowded spectrum
802.11b	802.11	Bit rate too low for many emerging applications	Widely deployed, higher range, Cheapest hardware
802.11g	802.11 and 802.11b	Limited number of collocated WLANs	High bit rate in 2.4 GHz spectrum
802.11n	802.11a, 802.11b and 802.11g	Difficult to implement	Highest bit rate

IEEE802.11b WLANs system provides the largest range but fails to provide the required data speed for many emerging applications. IEEE802.11g, n, ac, ax are becoming more popular due to the increased data speed they provide.

IEEE802.11 Network Performance Characterization

Throughput is the most important network performance statistics for characterizing IEEE802.11 WLANs. Network statistics parameters related to the topic of this chapter are presented in the following sections.

Throughput

Throughput is a measurement of the average rate that data (in bits) can be sent between one user and another (Henty, 2001). Throughput is the data in bits per second that the user experiences after overheads are removed. Poor throughput

causes dissatisfaction for the users as it will take more time to complete a task such as an upload or download on the network.

Poor throughput is always associated with longer round trip times (RTTs). RTT is the time required for a signal pulse or packet to travel from a specific source to a specific destination and back again (Ali and Khuder; 2012). Poor throughput and long RTTs are very uncomfortable for the users hence network designers make efforts to avoid such conditions.

The throughput and RTT experienced by users on a network are dependent on how well the network was designed (Henty, 2001). When the SNR degrades, the throughput observed reduces appreciably and the delay experienced becomes longer. These conditions are unpleasant for WLAN users.

When calculating throughput the protocol overhead is usually not included. A Transmission control protocol (TCP) throughput rate of 1Mbps, implies that 125kilobytes of actual data

payload were sent between two network nodes (e.g. Client and Server) during one second, not including TCP, Internet Protocol, and Ethernet or IEEE802.11 headers.

Packet loss is more applicable to Universal datagram protocol (UDP) because in UDP the traffic sending node can send as much traffic as the system can handle without knowing how much of it will be lost unlike in TCP where all packets must be acknowledged and no data loss is expected to occur.

For the same network connection, the throughput can change greatly based on the protocol used for transmission, the type of data traffic sent as well as the quality (SNR) and data bandwidth of the network connection (Henty, 2001). Among these parameters that influence throughput, the SNR is the most prominent because a poor SNR can sometimes result in zero throughput.

Throughput is measured at the transport layer to accurately reflect the performance that a user will experience. This is why it is usually computed using the amount of data in the payload area of the highest protocol layer (e.g., UDP or TCP payload size) of the packets being transmitted.

Network traffic is described in terms of upstream or downstream traffic. Upstream traffic refers to data that flows away from the local computer or network toward the remote destination. Downstream traffic refers to data that flows to the user's computer or network. Traffic on most networks flows in both upstream and

downstream directions simultaneously because when data traffic is flowing in one direction, the network protocols usually send control traffic in the opposite direction.

Received Signal Strength Indication (RSSI)

In telecommunications, RSSI is a measurement of the power present in a received radio signal. Due to recent improvements, the RSSI on Windows is the RSSI reported from the Wi-Fi card. RSSI reads directly in dBm in relation to the signal strength and is usually negative. The lower the negative number the better the signal strength as illustrated in Table 4.

Signal to Noise Ratio (SNR)

When performing RF site survey, it's important to define how far an access point (AP) signal can go based on SNR ratio. The SNR at any instant in time varies with: (i) signal losses due to physical channel condition variations, (ii) variations in noise floor level and (iii) changes in received signal strength indication (RSSI) due to changes in distance or direction of the Client from the WLAN radio.

SNR in decibel (dB) is the signal level (in dBm) minus the noise level (in dBm) (Geier, 2008; Serano, 2013). It should be noted that the dB here merely represents a difference in two logarithmic

Table 4. Received signal strength indication (dBm) classification legend of WLANs

Subjective Score	Signal Strength range (dBm)	Signal Quality	Possible Coverage Worth
5	$-60 \leq RSSI \leq -20$	Excellent Signal	Excellent Coverage
4	$-75 \leq RSSI \leq -60$	Good Signal	Strong Coverage
3	$-85 \leq RSSI \leq -75$	Low Signal	Weak Coverage
2	$-90 \leq RSSI \leq -85$	Very Low Signal	Unacceptable coverage
1	$-90 \leq RSSI \leq -108$	No Signal	No Coverage

(Isiagbona and Obahiagbon, 2013; Sarkar and Sowerby, 2009)

values, such as dBm. By comparison, the dB is a dimensionless unit, used for quantifying the ratio between two values.

The measured SNR of an AP at the user device decreases as range increases because signal level is decreased by the corresponding free space loss between the user and the AP. This is also true for signals propagating from the user device to the AP. Increase in RF interference due to the presence of devices such as microwave oven, cordless phones, etc. which increases the noise level, also decreases SNR.

A higher SNR value implies a stronger RSSI in relation to the noise levels, thereby allowing higher data rates to be selected for transmission and fewer retransmissions will occur. This offers better throughput and shorter RTTs. A lower SNR requires WLAN devices to operate at lower data rates, which decreases throughput and increases delay.

Recent studies have shown that frequency diversity can lead to limitations in the accurate prediction of SNR hence effective SNR has been proposed and widely adopted as a metric for measuring wireless channel quality (Mohammed & Lili, 2016). About 20dB is recommended as the minimum SNR for defining the range boundary of each access point. SNR can be categorized into three namely: Strong signals ($SNR > 24dB$), Grey signals ($25dB > SNR > 18dB$) and Weak signals ($SNR < 19dB$) (Henty, 2001; Geier, 2008; Sarkar and Sowerby, 2009; Oghogho, 2014a).

Interactions BETWEEN TCP Throughput, Losses, Link Adaptation, and SNR in WLANs

The SNR is the predominant metric for determining when to change the data link rate (DLR) in WLANs (Metreaud, 2006). In TCP losses trigger congestion control algorithm which reduces the sending rate and ensures the retransmission of lost packets (Oghogho, 2014b).

Overall losses across the different layers in WLANs are due to (i) the varying nature of the wireless channels resulting in incorrect reception of channel symbols at the physical layers, (ii) packet collisions and inefficiency of error correction schemes or mechanisms for the received channel symbols and (iii) queuing process and buffer overflows at the IP layer (Moltchanov, 2010; Detti et al., 2011).

These overall losses have significant impact on the throughput observed for a particular application because link adaptation in WLANs determines the selected data rate used for transmission. In link adaptation, stations choose a data rate depending on underlying channel conditions which is predominantly the SNR sensed by the station. This process changes the throughput behaviour of WLANs significantly (Mahmood, 2010). Link adaptation enables stations to use higher data rates to transmit their frames as SNR increases thus throughput increases close to maximum channel capacity.

The DLR variations which are caused by channel condition variations and losses in different layers have effects on the average throughput attainable for a given average SNR and the variation in throughput observed (Metreaud, 2006).

Cross Layer Modelling Principles

The Physical, data link, network, IP, transport and application layers have different losses associated with them (Moltchanov, 2012). Researchers have suggested that cross-layer modelling principles can provide the practical methodology to evaluate: (i) the effects of wireless channel characteristics, (ii) channel adaptation mechanisms and (iii) buffering process at the IP layer on the throughput of TCP connections sharing a wireless bottleneck (Moltchanov, 2012).

Three basic steps are involved in Cross-layer modelling: (i) wireless channel modelling, (ii) cross-layer extension of the wireless channel of interest to the layer of interest (iii) performance

evaluation at the layer of interest. We can replace a mathematical model that was applied at one layer by a better model at another higher layer in order to obtain better results of the overall performance of the WLAN system (Moltchanov, 2012).

The cross layer modelling of the aggregate performance of the IEEE802.11 WLAN system is difficult to model analytically. The performance that a given application provides is a complex function of the properties and interactions between the traffic, environmental conditions, protocols, etc. which are usually very difficult and complicated to analytically model (Moltchanov, 2010).

This process can be simplified by carrying out extensive measurements of an important network metric such as throughput at a higher layer (e.g. transport layer) while varying the RSSI at a lower layer (e.g. the physical layer) so as to provide data that aggregately represents information of the WLAN system performance over different layers in real environments.

All processes involved between the lower layer and the higher layer where measurement is taken are implicitly taken into account regardless of whether they can or cannot be isolated or separately recognised (Oghogho et al 2014a). An empirical approach simplifies the model and throughput can be directly predicted from SNR calculations.

Research That Modelled Throughput Dependence on SNR Only

In this section, empirical findings of some researchers using cross layer modelling principles to model the dependence of throughput against the received signal (either RSSI or SNR) are discussed.

Henty's Models

Henty (2001) developed a linear throughput model from an empirical study which was compared with results from measured data for different environments. The models predict the throughput as a

function of SNR only. There are three parameters that must be specified:

1. $T_{\max}$, the throughput experienced in ideal circumstances (that is under maximum signal to noise ratio and without interference).
2. A or α , a “slope” or rate of drop-off as the signal to noise ratio decreases.
3. T_0 or SNR_0 , Intercept points for the model. SNR_0 is the SNR when throughput falls to zero Mbps.

Below a critical SNR represented as SNR_C , the throughput observed shows a linear drop. Henty (2000) formula for the linear throughput model is given in equation 1.

$$T = \begin{cases} T_{\max} & \text{if } SNR > SNR_C \\ A * SNR - T_0 & \text{if } SNR \leq SNR_C \end{cases} \quad (1)$$

$T_{\max}$ (a critical throughput value), A and T_0 are all vendor and application specific. They are needed to predict the throughput of the WLAN for non-ideal situations. When the SNR drops below SNR_C , the throughput falls with a slope “ A ” and drops to a throughput “ T_0 ” when the SNR drops to 0dB. The value of SNR_C is the point of intersection of the two lines of the model. From equation 1, SNR_C can be obtained from $T_{\max}$, A and T_0 values as shown in equation 2.

$$SNR_C = \frac{T_{\max} + T_0}{A} \quad (2)$$

Henty (2001) also presented an exponential throughput model. Above a critical SNR value the throughput predicted is close to a maximum ($T_{\max}$). Below the critical SNR, the throughput drops exponentially to zero. The formula used for the exponential model is given in Equation 3.

$$T_1 = T_{\max} \left[1 - \exp(-\alpha (SNR - SNR_0)) \right] \quad (3)$$

The values for $T_{\max}$, α and SNR_0 can be tuned by measurement. They are also application and vendor specific. $T_{\max}$ is the WLAN throughput under ideal conditions. α is the slope of the exponential curve and determines the rate at which the exponential curve falls off. SNR_0 is the SNR value at which the WLAN shows zero throughput.

For two users or two Clients, Henty (2001) introduced T_{loss} factors into the throughput prediction models to adjust the single user throughput to match the actual throughput in the presence of a second user. The loss factor is based on the path loss from Client one (C_1) to the Client two (C_2) and is represented by $(PL(C_1, C_2))$. A major draw-back in this method is the difficulty in estimating the loss factors under other scenarios.

Using Matlab Henty (2001) presented simplified throughput equations in Mbps for two different vendors from their data as shown in equations 4-5 for WaveLAN and 3Com respectively.

$$T = T_1 (SNR_1) - 0.000309 (T_{\max} - T_1 (SNR_2)) - 0.00384 (PL(C_1, C_2)) + 0.0918 \quad (4)$$

$$T = T_1 (SNR_1) - 0.000072 (T_{\max} - T_1 (SNR_2)) - 0.00646 (PL(C_1, C_2)) + 0.0647 \quad (5)$$

Metreud Throughput Models

Metreud (2006) presented models which predict the average throughput as functions of the average received power. The models are single user models but they consider different types of channels for IEEE802.11b and IEEE802.11g WLAN Systems.

Metreud One Tap Constant Channel Model

This model represents an ideal channel used as a baseline for comparing throughput measured with more realistic channels. The channel is a representation of the maximum throughput that can be achieved for wireless devices. The piecewise linear model for the one tap constant channel describing the maximum achievable throughput (Mbps) for IEEE802.11b and IEEE802.11g WLANs are given by equations 6 and 7 respectively.

$$S_{ave(b)}(p) = \begin{cases} 6.15 & p > -84.73 \\ 0.94p + 86.04, & -91.25 < p \leq -84.73 \\ 0 & p \leq -91.25 \end{cases} \quad (6)$$

$$S_{ave(g)}(p) = \begin{cases} 29.15 & p > -72.82 \\ 1.51p + 138.79, & -91.18 < p \leq -72.82 \\ 0 & p \leq -92.18 \end{cases} \quad (7)$$

Where p is the received power (RSSI) in dBm.

Metreud One-Tap Model A Channel

This is a one-tap Raleigh fading channel having only one propagation path hence it is not a realistic channel. The piecewise linear model for the one tap Raleigh fading channel describing the maximum achievable throughput (Mbps) for IEEE802.11b and IEEE802.11g WLANs are given by equations 8 and 9 respectively.

$$S_{ave}(p) = \begin{cases} 6.06 & p > -76.42 \\ 0.38p + 35.37, & -92.21 < p \leq -76.42 \\ 0 & p \leq -92.21 \end{cases} \quad (8)$$

$$S_{ave}(p) = \begin{cases} 26.94 & p > -65.84 \\ 1.3p + 101.30, & -89.69 < p \leq -65.84 \\ 0 & p \leq -89.69 \end{cases} \quad (9)$$

Metreud Multi-Tap Model B Channel

This is a multi-tap, two cluster multipath model used to represent an indoor residential area. The piecewise linear model for the multi-tap Model B channel describing the maximum achievable throughput (Mbps) for IEEE802.11b and IEEE802.11g WLANs are given by equations 10 and 11 respectively.

$$S_{ave}(p) = \begin{cases} 6.12 & p > -78.55 \\ 0.54p + 48.16, & -89.98 < p \leq -78.55 \\ 0 & p \leq -89.98 \end{cases} \quad (10)$$

$$S_{ave}(p) = \begin{cases} 26.61 & p > -65.49 \\ 1.12p + 99.92, & -89.27 < p \leq -65.49 \\ 0 & p \leq -89.27 \end{cases} \quad (11)$$

Metreud Multi-Tap Model C Channel

This is a multi-tap, and a slightly harsher channel than channel B having more taps and a greater RMS delay spread. The piecewise linear model for the multi-tap Model C channel describing the maximum achievable throughput (Mbps) for IEEE802.11b and IEEE802.11g WLANs are given by equations 12 and 13 respectively.

$$S_{ave}(p) = \begin{cases} 6.14 & p > -79.40 \\ 0.62p + 55.21, & -89.33 < p \leq -79.40 \\ 0 & p \leq -89.33 \end{cases} \quad (12)$$

$$S_{ave}(p) = \begin{cases} 26.71 & p > -66.33 \\ 1.16p + 103.79, & -89.32 < p \leq -66.33 \\ 0 & p \leq -89.32 \end{cases} \quad (13)$$

Only UDP traffic was used and interfering sources and the effect of humans were completely

isolated in their work hence they give higher values than what will be expected in real-life measurements.

Oghogho, Edeko and Emagbetere TCP Upstream Throughput Models

Oghogho et al (2014a) and Oghogho et al (2015a) presented IEEE802.11b WLAN throughput models which describe single and multiple users TCP upstream throughput as functions of SNR only for all SNR, strong signals (SNR>24dB), grey signals (18<SNR<25dB) and weak signals (SNR<19dB).

The single user models are shown in equations 14-17. C, C_1 and C_2 are model constants while a_1, a_2 and a_3 are model coefficients.

$$(General) TCP_{up} T_s = f(SNR) = \begin{cases} C_1 & SNR > 38dB \\ a_1 SNR + a_2 SNR^2 + a_3 SNR^3 & 39dB > SNR > 16dB \\ |a_1 SNR + a_2 SNR^2 + a_3 SNR^3 - C_2| & SNR < 17dB \end{cases} \quad (14)$$

$$(Strong) TCP_{up} T_s = f(SNR) = SNR^{a_1} \quad (15)$$

$$(Grey) TCP_{up} T_s = f(SNR) = a_1 SNR \quad (16)$$

$$(Weak) TCP_{up} T_s = f(SNR) = \begin{cases} a_1 SNR^2 + a_2 SNR^3, & 19dB > SNR > 11dB \\ 0 & SNR \leq 11dB \end{cases} \quad (17)$$

Oghogho et al (2015a) multiple users models are shown in equations 18-21.

$$(General) TCP_{up} T_M = f(SNR) = C * SNR^{a_1} \quad (18)$$

$$(Strong) TCP_{up} T_M = f(SNR) = a_1^{SNR} \quad (19)$$

$$(Grey)TCP_{up}T_M = f(SNR) = e^{\left(\frac{a_1}{SNR}\right)} \quad (20)$$

$$(Weak)TCP_{up}T_M = f(SNR) = e^{\left(\frac{a_1}{SNR}\right)} \quad (21)$$

Oghogho et al (2015b) presented empirical probability models for predicting IEEE802.11b WLAN TCP upstream throughput for single and multiple users. These models predict the probability that the TCP upstream throughput falls within a certain range based on the SNR observed.

For a single user on the network, Z values can be obtained using model equations 22-25 for all SNR, Strong signals, Grey signals and Weak signals respectively. X is the TCP upstream throughput value whose probability is to be predicted and C is the correction factor they introduced into the respective equations.

$$Z = \frac{x - 5.1038}{1.81327} + C, (0 \leq x \leq \infty) \quad (22)$$

$$Z = \frac{x - 5.8942}{0.64389} + C, (0 \leq x \leq \infty) \quad (23)$$

$$Z = \frac{x - 2.2078}{1.54209} + C, (0 \leq x \leq \infty) \quad (24)$$

$$Z = \frac{x - 0.736}{0.67621} + C, (0 \leq x \leq \infty) \quad (25)$$

For a multiple users on the network, Z values can be obtained using model equations 26-29 for all SNR, Strong signals, Grey signals and Weak signals respectively.

$$Z = \frac{x - 2.510255}{1.8888} + C, (0 \leq x \leq \infty) \quad (26)$$

$$Z = \frac{x - 2.991923}{1.7747314} + C, (0 \leq x \leq \infty) \quad (27)$$

$$Z = \frac{x - 0.7517}{1.07056} + C, (0 \leq x \leq \infty) \quad (28)$$

$$Z = \frac{x - 0.487813}{0.6485703} + C, (0 \leq x \leq \infty) \quad (29)$$

Oghogho, Edeko and Emagbetere TCP Downstream Throughput Models

Oghogho et al (2015c) presented IEEE802.11b WLAN throughput models which describe single user TCP downstream throughput as functions of SNR only. Equations 30-33 show the different model equations for General model (all SNR), Strong signal model, Grey signal model and Weak signal model respectively.

$$\begin{aligned} (General)TCP_{down}T_s = f(SNR) = \\ SNR^{a_1}, \quad SNR > 15dB \\ SNR^{a_1} + C_1, 16dB > SNR > 8dB \\ 0, \quad SNR < 9dB \end{aligned} \quad (30)$$

$$\begin{aligned} (Strong)TCP_{down}T_s = f(SNR) = \\ C_2, \quad SNR > 64dB \\ C_3, \quad 64dB > SNR > 56dB \\ SNR^{a_1}, 57dB > SNR > 24dB \end{aligned} \quad (31)$$

$$(Grey)TCP_{down}T_s = f(SNR) = SNR^{a_1} \quad (32)$$

$$(Weak)TCP_{down}T_s = f(SNR) = \begin{cases} a_1 SNR, & SNR \geq 7dB \\ 0, & SNR < 7dB \end{cases} \quad (33)$$

Oghogho et al (2016) presented IEEE802.11b WLAN throughput models which describe multiple user TCP downstream throughput as functions of SNR only. Equations 34-37 show the different model equations.

$$\begin{aligned} & (General) TCP_{down} T_M = \\ & f(SNR) = a_1 SNR + a_2 SNR^2, SNR > 9dB \end{aligned} \quad (34)$$

$$\begin{aligned} & (Strong) TCP_{down} T_M = \\ & f(SNR) = a_1 SNR + a_2 SNR^2, SNR > 24dB \end{aligned} \quad (35)$$

$$\begin{aligned} & (Grey) TCP_{down} T_M = \\ & f(SNR) = a_1 \ln(SNR), 18dB < SNR < 25dB \end{aligned} \quad (36)$$

$$\begin{aligned} & (Weak) TCP_{down} T_M = \\ & f(SNR) = a_1 SNR, SNR > 19dB \end{aligned} \quad (37)$$

Oghogho et al (2015d) presented empirical probability models for predicting IEEE802.11b WLAN TCP downstream throughput for single and multiple users. For a single user on the network, Z values can be obtained using model equations 38-41 for all SNR, Strong signals, Grey signals and Weak signals respectively. x is the TCP downstream throughput value and C is the correction factor they introduced into the respective equations.

$$Z = \frac{x - 5.2323}{1.33735} + C, (0 \leq x \leq \infty) \quad (38)$$

$$Z = \frac{x - 5.7489}{0.60438} + C, (0 \leq x \leq \infty) \quad (39)$$

$$Z = \frac{x - 3.3915}{1.37022} + C, (0 \leq x \leq \infty) \quad (40)$$

$$Z = \frac{x - 2.1143}{1.51961} + C, (0 \leq x \leq \infty) \quad (41)$$

For multiple users on the network, Z values can be obtained using model equations 42-45 for

all SNR, Strong signals, Grey signals and Weak signals respectively.

$$Z = \frac{x - 1.59385}{2.5025} + C, (0 \leq x \leq \infty) \quad (42)$$

$$Z = \frac{x - 1.48491}{2.6833} + C, (0 \leq x \leq \infty) \quad (43)$$

$$Z = \frac{x - 1.8242}{1.81778} + C, (0 \leq x \leq \infty) \quad (44)$$

$$Z = \frac{x - 1.4034}{1.55312} + C, (0 \leq x \leq \infty) \quad (45)$$

FUTURE RESEARCH DIRECTIONS

The models presented in this chapter focused on those that will enable researchers and WLAN users to estimate TCP throughput for various observed values of SNR when there is a single or there are multiple users on the network. To fully describe the behaviour of throughput there is the need to:

1. Consider models specifically developed for other IEEE 802.11 WLAN systems based on other standards (e.g. IEEE 802.11g, n, e, ac, ax, etc.) as functions of SNR only.
2. Consider models specifically developed from other protocols (e.g. UDP) as functions of SNR only.

This will help to facilitate the development of a software tool with a graphic User interface to aid accurate prediction of throughput over a wide range of SNR for different IEEE802.11 WLAN standards, protocols, environments, users, vendors, etc. The Network designer will only need to carry out an RSSI and noise floor level survey of their environments and the tool will estimate the throughput after the appropriate network parameters have been fed into the software.

CONCLUSION

In this chapter the author presented the dependence of Throughput on SNR in IEEE 802.11 WLAN systems. The author emphasized that the throughput experienced by the users is a major parameter for characterizing WLAN performance. The multiple communication data rates specified by the physical layer which vary depending on the quality of the current link (basically the SNR observed) was shown to appreciably influence the throughput experienced by the users. Finally, recent research findings which apply cross modelling principles to model the dependence of throughput on SNR was presented along with future directions in this research area.

KEY TERMS AND DEFINITIONS

Cross Layer Modelling: It is a type of modelling that involves three basic stages namely: (i) wireless channel modelling, (ii) cross-layer extension of the wireless channel of interest to the layer of interest (iii) performance evaluation at the layer of interest.

Signal to Noise Ratio (SNR): It is a network metric measured in decibel (dB) and is equal to the signal level (in dBm) minus the noise level (in dBm).

Throughput: It is a measurement of the average rate that data (in bits) can be sent between one user and another.

University of St. Gallen, Switzerland

INTRODUCTION

The abilities of the brain, a complex, nonlinear and parallel computer, to learn, memorize and generalize, have motivated research in biological neural systems, referred to as “artificial neural systems” (ANNs) (Engelbrecht, 2007, p. 5). ANNs are a powerful technique for multivariate dependence analysis. The current capabilities of modern computing power and storage space allow for easy solutions of problems with a single objective by means of moderate-sized ANNs (Ibid.). Unlike other traditionally used techniques in economics and finance, artificial neural networks (ANNs) do not necessarily rely on assumptions about the population distribution (Shachmurove, 2003). Furthermore, the universal approximation theorem (Cybenko, 1989; Funahashi, 1989) postulates that an ANN with one hidden layer is capable of approximating any continuous function.¹ Due to these facts, ANNs are becoming an increasingly attractive and flexible analytic tool for applications in the area of economics and finance. The purpose of this article is to present such important applications with an emphasis on recent research trends.

BACKGROUND

Please see the Artificial Neural Networks entry, this volume for further discussion on ANNs basics. A frequently used ANN in economics and finance is the feedforward ANN. In this architecture, information stringently flows from the neurons situated in the input layer to the neurons in the

subsequent layers without any feedback connections. Each node is a neuron except for the input nodes. Rather than moving directly from input to output, new neurons as weighted combinations of input variables located in a hidden layer are created. This is a common ANN feature that ensures the achievement of modelling flexibility. When all neurons of a preceding layer are fully connected with all neurons in the subsequent layer, the ANN is referred to as “a multilayer perceptron” (MLP).

Similarly to MLPs, ANNs of a radial basis function type (RBF) (Broomhead & Lowe, 1988) are universal function approximations (Haykin, 1998) that have been a frequent choice in business applications. The difference between MLP and RBF ANNs consists in the type of approximation to non-linear mapping they deliver. The RBF delivers a local approximation while the MLP – a global one (Haykin, 1998). The detailing of contributions focused on the technical specifics of ANNs concerning optimization and architecture is beyond the scope of this article. Instead, the interested reader is referred to their comprehensive coverage in the books of Haykin (1998), Engelbrecht (2007), Haykin (2009) and Rojas (2013), while McNelis (2005), Zhang (2008), and Alexandridis and Zapanis (2014) contain applications in the area of economics and finance.

MAIN FOCUS OF THE ARTICLE

The purpose of this section is to survey important applications of ANNs in economics and finance. Emphasis has been laid on recent research trends in contributions in which ANNs are the main em-

DOI: 10.4018/978-1-5225-2255-3.ch575

pirical method or are combined with alternative research tools.

Applications of ANNs for Prediction

A major part of the ANN contributions in the area of economics and finance is dedicated to predictions. The implemented input data are either technical (for example, historical data of assets' statistical distribution moments) or fundamental (for example, data on the current economic activity). A tendency to focus on robustness checks is followed by some authors: (1) to compare the performance of ANNs to alternative methods, such as ARCH/GARCH models, which are appropriate for financial and economic data that frequently exhibit volatility clustering; (2) to combine them in hybrid models, or (3) to implement several ANN architectures in order to encourage the choice of the optimal one. In this section, such contributions are given priority over works that implement a single ANN model because of their goal of finding the best solution from several alternatives.

Falat et al. (2015) studied the volatility dynamics of the EUR/GBP currency with the traditionally applied in such research setting statistical approach that relies on ARCH and GARCH models, as well as several RBF ANN architectures. The authors reported higher but not considerable accuracy for the statistical approach. However, Falat et al. (2015) attributed this to factors such as their non-ideal but improvable optimization strategy. Kristjanpoller et al. (2014) combined ANNs and a GARCH model in a hybrid ANN-GARCH model for predicting the volatility of three emerging Latin American stock markets. On the basis of several robustness checks, the authors reached the conclusion that the hybrid model improved the performance of the GARCH model with respect to their sample. Kristjanpoller and Minutolo (2015) obtained analogous results concerning the spot and future volatility of gold. They also proposed an algorithm that incorporated variables in their model only if they improved it, assessed in terms of a measure of the model error.

Abrishami and Varahami (2011) implemented, for the prediction of gas prices, the popular in financial and economic research multilayer feedforward ANN and a group method of data handling (GMDH) ANN. The latter architecture is based on pattern recognition and can be used as a refined alternative to the traditional technical analysis (Abrishami & Varahami, 2011). The authors proposed a hybrid ANN containing GMDH and rule-based expert system modules. They reached the conclusion that it performed better during the recent 2008 financial crisis. Similarly, based on a GJR-GARCH ANN model for predicting the volatility of the NASDAQ Composite Index, Monfared and Enke (2014) reached the conclusion that hybrid models were appropriate for forecasting extreme events because the structure of volatility becomes more complex. ANNs should be avoided in low-volatility periods because they bring unnecessary complexity (Monfared & Enke, 2014).

A class of ANN models with a growing number of financial and economic applications is the wavelet ANNs, proposed by Zhang and Benveniste (1992). They combine a wavelet function as an activation function and a classical ANN. Bernard et al. (1998) explained their superior performance with their lower computational cost if wavelets were used instead of other activation functions. At the same time they preserve their approximation capacity due to their ANN component. Alexandridis and Zapranis (2013 a,b) demonstrated that wavelet ANNs could be efficiently used for weather derivative pricing and modelling as well as for the prediction of the prices of financial weather derivatives. Alexandridis et al. (2008) also reported accurate performance of wavelet ANNs for predicting crude oil returns. The interested reader is referred to the book of Alexandridis and Zapranis (2014) for a comprehensive account of the model identification framework for utilizing wavelet ANNs in various applications.

Sermpinis et al. (2016) proposed two hybrid ANNs: an adaptive evolutionary multilayer per-

ceptron (aDEMLP) and an adaptive evolutionary wavelet neural network (aDEWNN). The authors compared their performance to the traditionally applied MLP benchmark for forecasting and trading of the Dow Jones Industrial Average, iShares NYSE Composite Index Fund and SPDR S&P 500 exchange-traded funds. Sermpinis et al. (2016) demonstrated the superior accuracy of their hybrid models compared to the traditionally applied MLP, as well as wavelet ANN, autoregressive moving average models, a smooth transition autoregressive model and a random walk model. A distinct contribution of their work is that the adaptive hybrid ANNs they propose are deprived of any data-snooping bias.

Higher-order artificial neural networks (HO-ANNs) form part of another new direction in the ANN literature that deals with their shortcoming that, without the application of additional methods,² they are a “black box”, which means that the decision-making behind the results is challenging to explain. Zhang (2008) refers to HOANNs as “open box”, due to the transparent mapping of each neuron and weight to a functional variable and coefficient. This book, edited by Zhang (2008), contains a collection of the few contributions in finance and economics that apply HOANNs, for example for exchange rate, stock return, electricity load demand and price prediction.

Among the other ANNs applications can be mentioned: inflation forecasting (Nakamura, 2005); fundamental analysis and prediction of stock returns based on financial ratios (Yildiz & Yezegel, 2010); financial distress prediction (Chen & Du, 2009; Chen et al., 2009); prediction of public expenditure (Radulesku et al., 2015); risk management (Krollner, 2011; Lai et al., 2007); trading strategies (Zhang et al., 2007); real gross domestic production and industrial production (Aminian et al., 2006); sovereign debt crises (Fioramanti, 2008); and forecasting of the future value of financial assets (Giebel & Rainer, 2013).

Applications of ANNs for Classification

Classification is a supervised learning statistical problem that consists in extracting selected information from finite samples. Similarly to ANN applications for predictions, its usefulness lies in the possibility that its results can be used for subsequent decision-making. ANNs for classification in the area of finance and economics are predominantly used for analysis of the fraudulent behaviour and insolvency of economic agents (for example, customers and banks). The purpose of this section is to present such recent common applications.

Baesens et al. (2005) compared the performance of various ANN models and a proportional hazards model in relation to a data set with 15,000 observations for personal loans. The authors reached the conclusion that with respect to the chosen data set, ANNs perform better at distinguishing good from bad borrowers. Kirkos et al. (2007) used various competing statistical methods for detecting fraudulent financial statements: an ANN, a decision tree (Arminger et al., 1997) and a Bayesian belief network (Pearl, 1986), while Chen (2016) also implemented a support vector machine (Vapnik, 1995) with the same research purpose. In both studies the implemented traditional ANNs are not the best performing method. Since ANNs have a universal approximation property, and, similarly to the conclusion of Falat et al. (2015), their performance may be enhanced by an improved optimization strategy or by the application of a different ANN architecture. For example, Ravisankar et al. (2011) applied the probabilistic neural network (PNN) proposed by Specht (1990), based on the Bayes classifier, in addition to the traditional classification methods (logistic regression, a support vector machine and a MLP ANN). The authors report a superior performance of the PNN for financial statement fraud detection after applying the standard for

classification applications selection of the most significant inputs and cross-validation. The interested reader is referred to the survey of Ngai et al. (2011) for a comprehensive account of the existing data mining techniques in addition to ANNs for detection of financial fraud.

Applications of ANNs for Modelling

ANNs are applied less frequently in economics and finance for modelling. One of their applications is for modelling of bounded rational adaptive artificial agents. This approach emerged in response to the observed inconsistency of the assumption for agents' full rationality (see, for example, Allais, 1953). Introduced by Simon (1955), the concept "bounded rationality" relies on the realistic assumption that agents produce decisions based on the available and not complete information. In this setting, the ANN's neurons are interpreted as agents that receive information from the environment and produce decisions on this basis.

Repetitive games are a well-developed strand of the mathematical modelling literature for studying human behaviour. Chernobelskiy et al. (2013) applied an ANN for simulating agents' behaviour with different levels of sympathy and selfishness. This is a more realistic approach than the traditional assumption in economic models that participants take decisions that maximize their personal utility. Sgroi and Zizzo (2008) studied the question of whether ANNs can learn to play a $n \times n$ game by playing a finite set of other $n \times n$ games. Svalestuen et al. (2015) proposed an application of an ANN and evolutionary game theory (EGT) for predicting social behaviour through multi-agent-based simulation. The applied ANN adapts its weights by using the EGT "learning-by-imitation" method in order to reflect the agent's decision-making rule. This simulation-based modelling strategy can be integrated into a decision support system for fair policies for stakeholders (Svalestuen et al., 2015).

The prospect theory of Kahneman and Tversky (1979), which builds on psychological biases, is

another response to the controversial assumption of agents' full rationality and marks the emergence of behavioural finance and behavioural economics. Furthermore, the advent of non-invasive human brain imaging techniques makes it possible to study biologically economic theories of choice and the emergence of neuroeconomics as new research fields. Farmer and Lo (1999, p. 9991) assess positively the prospects of this trend with respect to finance:

One of the most promising directions is to view financial markets from a biological perspective and, specifically, within an evolutionary framework in which markets, instruments, institutions, and investors interact and evolve dynamically according to the "law" of economic selection. Under this view, financial agents compete and adapt, but they do not necessarily do so in an optimal fashion. Evolutionary and ecological models of financial markets are truly a new frontier whose exploration has just begun.

The works of Wang, (2002), Wong and Wang (2006), and Rustichini and Padoa-Schioppa (2015) can be given as examples of ANN applications in this context.

Padoa-Schioppa (2008, p. 451) reflects on the future of neuroeconomics:

If neuroscience will contribute to economics, it will do so by the way of psychology. In other words, discoveries about the brain will hopefully lead to better theories of thought, which in turn will hopefully lead to better theories of choice behaviour. The syllogism is based on two premises – that neuroscience can contribute to psychology, and that psychology can contribute to economics. [...] It thus follows that neuroscience can contribute to economics. Notably, this proposition is a statement of possibility. Whether any discovery about the brain will in fact lead to better economic theories is ultimately an empirical question. Current examples might not be the most compelling, but the field is in its infancy and time will tell.

FUTURE RESEARCH DIRECTIONS

A future trend in the evolution of ANN research in economics and finance will build on a major difference between ANNs and the human brain: the principle of self-organization of the latter (Kelso, 1995), which ensures its adaptability. Traditional ANNs, for example the neuron-fixed feedforward networks, evolve according to a pre-defined architecture and are not self-organized. The elaboration of new adaptive neural network models is promising for applications in economics and finance because they successfully adapt to non-stationary input data. That is, the ANN system remains optimal over time because its parameters change in line with the input. For example, Patra et al. (2015) proposed an adaptive local linear optimized RBF ANN model for financial time series prediction. Their model has displayed superior performance than the traditional architectures based on an RBF and MLP.

An essential and integral part of any model in economics and finance is its interpretation. A common misconception concerning ANNs is the claim that they are a “black box”, wrongly attributed to their failure to explain the contribution of each independent variable in the prediction process. However, although undertaken by very few authors, studies that develop techniques for tracking the explanatory capacity of ANNs exist and hold great promise for their wider future successful applicability in different business fields. Olden et al. (2004) and Gevrey et al. (2003) surveyed and tested the main existing methods for explaining the capacity of ANNs. Paliwal and Kumar (2011) proposed a new method for ranking the relative importance of each input variable in the ANNs based on the interquartile range of the empirical distribution of the network weights that connect input to hidden nodes. The authors also considered the important question in economics and finance of how their method would perform when the input data exhibit multicollinearity. Paliwal and Kumar

(2011) reached the conclusion that it performs well in the presence of such data provided that the sample size is big enough.

The observed tendency towards increased availability of big data provides opportunities for more refined testing of existing theories and exploration of new research questions in economics and finance that previously were impossible to answer based on macro-level aggregate data. Furthermore, it can be expected that big data statistical methods and topics from related fields will be adapted for economic and financial ANN applications. For example, the traditionally applied in social marketing sentiment analysis or opinion mining has been applied for analysis of financial news by Heston and Sinha (2014). Another application of ANN that is potentially extendable to economic and financial big data was studied by Chen et al. (2010) and Zhu et al. (2010). Both contributions rely on game theory in order to study social networks. The interested reader is referred to the presentation of Roncalli (2014) in section “Additional readings” for further references and a comparison of the performance of ANN and other methods in various big data financial applications (bond scoring, asset picking, trend filtering, index tracking, technical analysis, mean reverting).

As stated by David Hendry based on Mayer-Schönberger and Cukier (2013), all authors cited by Taylor et al. (2014, p. 6), “much work using Big Data is essentially descriptive, dealing with correlation rather than causality. [...] if economics cannot seek causality, it similarly loses one of its mainstays [...]” Consequently, methods that enhance and adapt the explanatory capacity of ANNs to big data business applications have promising potential.

Deep learning applications can also be expected to attract professionals’ and scholars’ attention due to increased availability of high quality data. A selection with examples of such recent applications is provided in section “Additional readings”.

CONCLUSION

There is well-documented evidence that the observed economic and financial phenomena frequently have a complex non-linear behaviour. ANNs are attracting growing research interest due to their capacity to deal with the modelling challenges of this type of data. There is a tendency in the new research contributions to combine ANNs and other methods in more flexible hybrid models. Consequently, emphasis is placed on fine-tuning ANNs in order to add power to their explanatory capacity. A parallel tendency with a similar goal is to compare the performance of ANNs to other Alternative models.

An essential and integral part of any model in economics and finance is its interpretation. Although undertaken by very few authors, studies that develop techniques for tracking the relative contribution of each input variable of ANNs have exhibited a tendency towards a gradual increase in recent years. These particular studies hold great promise for the wider future successful applicability of ANNs in different business fields.

Finally, the tendency towards increased availability of data with much refined granularity opens new research opportunities. Both more refined testing of existing theories and exploration of new economic and financial research questions, as well as adaptation of methods and topics of related to the finance and economics research fields, can be expected to draw scholars' attention.

KEY TERMS AND DEFINITIONS

Artificial Neural Network Architecture (Topology): This concept involves decision-making concerning the size and number of the ANN layers, as well as the design of the connections among the ANN units.

Data Snooping: Denotes the use of statistical inference methods for detecting statistically significant patterns without prior theorizing and formulating hypotheses regarding their causal relationship.

Deep Learning: A branch of machine learning to whose architectures belong deep ANNs. The term “deep” denotes the application of multiple layers with a complex structure.

Explanatory Capacity of Artificial Neural Networks: It consists in the implementation of methods that are able to determine the relative contribution of each ANN input variable to the ANN output. See Gevrey et al. (2003) for further details.

Multicollinearity: This concept explains the situation in regression analysis when two or more of the independent variables are moderately to highly correlated. Consequently, the regression results are biased.

Stationarity: A time series is stationary when its statistical distribution moments do not change over time.

Supervised Learning: It consists in learning from data with a known-in-advance outcome that is predicted based on a set of inputs, referred to as “features”.

ENDNOTES

- ¹ This statement is true if a global minimum can be reached for each concrete ANN application.

INTRODUCTION

Perspectives of Chapter

Knowledge discovery in datasets (KDD), the process of finding non-obvious patterns or trends in datasets primarily to assist in understanding complicated systems (Mannila, 1996), leveraging computational pattern recognition methods to predict, describe, classify, group, and categorization data (Jain, Duin, & Mao, 2000). The nonlinearity of ANNs lend to modeling complex data structures; however, this also results in ANNs being complex and opaque to many users (Weckman, et al., 2009). While ANNs see application in business applications, some hesitation and misconceptions appear due to the ‘black-box’ nature of ANNs (Dewdney, 1997); hence traditional statistical-based models are far more used in practice. Although some interpretability aspects exist when applying ANNs (de Marchi, Gelpi, & Grynawski, 2004), it should be noted that the interpretability of ANNs is subjective relative to other commonly used tools.

Objectives of Chapter

ANNs methods are interconnected networks of nodes, which are trained on patterns in data through statistical learning methods (Jain, Duin, & Mao, 2000). Although ANNs are computation-

ally complex, inherently ANNs are statistical in nature and epistemologically similar in function to Bayesian (Beck, King, & Zeng, 2004) and likelihood methods (Verikas & Bacauskiene, 2002). Various software packages are now available for practitioners, including NeuroDimensions (2005), Matlab (2010), JMP (Sall, Lehman, Stephens, & Creighton, 2012), and R (2008). The objective of this chapter is to provide readers with a general background of ANNs, their business applications, and developing quality ANN models. The target audience is intended to be readers who may not be familiar with this form of mathematical modeling practice but may want to pursue it for their business need.

In Young, Bihl, and Weckman (2014), the authors provided a brief overview of ANNs and their applications in business. Herein, the authors have revised this discussion and included new material on ANN architectures and an example end-to-end analysis of business data using ANNs with the JMP13 Pro platform.

Biological Inspiration of ANNs

ANNs are computational machine learning models that are neurologically inspired with the intent of representing complex non-linear input and output relationships. The earliest known development of the ANN model was in the 1940s (McCulloch &

Figure 1. Biological Neuron (Young, Holland, & Weckman, 2008)

Pitts, 1943), with the fundamental building block of the ANN model being the neuron. Figure 1 displays a basic sketch of the biological neural network model (Neuralpower, 2007).

Computational ANNs extend biological neuron models by considering multiple interconnected nodes termed “neurons” which employ statistical methods to learn patterns between inputs and outputs (Jain, Duin, & Mao, 2000). Through organizational and iterative principles, connection weights between neurons, inputs and outputs are computed to learn a nonlinear input-output relationship (Jain, Duin, & Mao, 2000).

BACKGROUND: ANN PROPERTIES

Underlying Artificial Neuron Operations

Perceptrons, aka “nodes”, computationally inspired models of biological neurons, employ mathematical and statistical methods to determine a mapping between independent inputs (X_1 , X_2 , X_3 , and X_m) and a dependent variable (Y). In operation, as represented in Figure 2 and with an example linear activation function, perceptron connection weights (W_1 , W_2 , W_3 , and W_m) and

Figure 2. Artificial Neuron, adapted from (Young, Holland, & Weckman, 2008; Li, Artificial neural networks and their business applications, 1994)

bias (B) are determined through iterative methods such as gradient descents. Weights represent the determined strength of the association between independent and dependent variables. Weights can be positive, negative, or zero; the weighted sum is then processed by the neuron's activation function and then sent through the rest of the network.

Table 1 contains the three most commonly used activation functions for a single perceptron (Duch & Jankowski, 1997) along with the step function. While the step function could be used, ANN training frequency employs gradient descents for learning which involve a derivative of the step function. Therefore, the hyperbolic tangent, linear, and logistic/sigmoid activation functions are more common due to their derivational advantages. Due to interconnections and training, an ANN using linear activation functions will still result in a nonlinear model.

To determine which activation to use, a trial-and-error procedure is required; however, the sigmoid function is the default for many operations. One simple ANN example is logistic regression whereby a single ANN neuron, a *perceptron*, with one input and one output node is essentially considered (Timmerman, et al., 1999).

Architectures

In operation, ANNs generally consist of three types of layers: input, hidden, and output. Layers between the input and output layers are typically termed 'hidden' because they act as 'black-box' transformations where the mechanism for prediction is not transparent to users (Olden & Jackson, 2002). The most commonly utilized ANN architecture in practice is the multilayer perceptron (MLP) model as seen in the neural interpretation diagram (NID) of Figure 3 (Özesmi & Özesmi, 1999). The four layer MLP ANN in Figure 3 uses hyperbolic tangent activation functions and, moving from left to right, one sees that the first layer (or input layer) is connected to the first hidden

Table 1. Common activation functions

Activation Functions	Definitions	Range
Hyperbolic Tangent	$\frac{e^x - e^{-x}}{(e^x + e^{-x})}$	(-1, 1)
Linear	x	$(-\infty, +\infty)$
Logistic/Sigmoid	$\frac{1}{(1 + e^{-x})}$	(0, 1)
Step	$\begin{cases} 0, & x < 0 \\ 1, & x \geq 0 \end{cases}$	(0, 1)

layer, with the output of the first hidden layer then feeding into any subsequent hidden layers, with the results passed to the output layer. In this diagram, solid lines represent excitation signals (or positive weights), dashed lines represent inhibitory signals (or negative weights), and line thickness reflect the magnitude of the weight. To determine a network's weights one trains the network, where the values and activation functions determine what relationships are passed through the network.

However, ANNs come in a variety of structures, as seen in Figure 4. Although detailing all methods available is beyond the scope of this overview, some of variants include probabilistic neural networks, evolutionary ANNs (Yao & Liu, 1997; Yao & Liu, 1998; Yao, 1999), radial basis function networks (Looney C., 1997), recurrent ANNs (Looney C., 1997), and convolution networks (Duda, Hart, & Stork, 2001), among many other methods. These methods largely differ by the nature of connections (feedforward or feedback), the presence of an output layer (e.g. learning vector quantization (LVQ) ANNs, a type of Self-Organizing Map (SOM), have only an input and hidden layer), and the nature of the learning rules (Jain, Mao, & Mohiuddin, 1996; Looney C., 1997, p. 368).

Figure 3. Multi-Layered ANN, adapted from (Young, Holland, & Weckman, 2008)

Figure 4. General Taxonomy of ANN Architectures, taken from (Bihl, 2015) and adapted from (Jain, Mao, & Mohiuddin, 1996) using the ANN families of (Looney C. G., 1997, p. 368)

DECISIONS IN DEVELOPING ANNs

Data Preprocessing Issues

Preprocessing steps include any necessary normalization, imputing missing values, and data quality checks. Practically, models should be trained with more data than free parameters, with ideal ratios of 10:1, 5:1 or 3:1 (observations to

free parameters), to prevent over-fitting (Schunn & Wallach, 2005). Conversely, one could penalize the performance index for every free parameter in a model (Myung, 2000; Grünwald, 2001). Additionally, understanding the class balance in the data is critical. If one aims to understand a minority class (e.g. loan defaults), strategies such as under-sampling (Liu, Wu, & Zhou, 2009) can be beneficial.

Data Partitioning Philosophies

As with any pattern recognition problem, one should avoid training and testing on the same observations; to avoid this situation, training, testing, and cross-validation observations should be sequestered (Zhang G. P., 2007). In building ANNs, one uses the training and test sets to build an ANN, with weights fine-tuned for performance, the validation set then evaluates final ANN accuracy (Zhang G. P., 2007).

Two issues exist in creating training/testing/validation data subsets: 1) selecting subset percentages, and 2) the data splitting method to create representative subsets. Consensus does not exist on subset percentages, as seen in Table 2. Multiple strategies also exist for appropriately selecting training/testing/validation observations (May, Maier, & Dandy, 2010); generally, these are either random or deterministic. Random selection is one of the most common methods (May, Maier, & Dandy, 2010); while deterministic means follow different philosophies (Wu, May, Dandy, & Maier, 2012), and include methods such as CADEX (Kennard & Stone, 1969), DUPLEX (Snee, 1977), and SSTATS (Mindrup, Friend, & Bauer, 2012).

SELECTING AND SPECIFYING ANN ARCHITECTURE

Overfitting is a known issue in ANNs, c.f. (Clark, 1999), therefore appropriately specifying the ANN architecture, such as the number of layers and nodes, is essential. An example of the importance

of proper architecture selection is presented in Figure 5, on a small dataset ($N = 27$, $N_F = 3$ data features, $N_c = 3$ classes). Here averaged results from 100 replications are presented. One can see that instantiating too few hidden nodes yields poor, but consistent, accuracy, while instantiating too many hidden nodes provides excellent training accuracy but poor testing accuracy on unseen observations, a condition of overfitting.

Selecting the appropriate number of hidden nodes, N_{Hidden} , involves both science and art; too few will not be accurate, while too many nodes introduce noise (Looney C., 1997). However, a variety of heuristics exist, see (Gao, Chen, & Qin, 2010), to facilitate this process. One basic and reasonable ANN heuristic involves instantiating an amount proportion to the number of classes:

$$N_{Hidden} = aN_c$$

where a is a user specified constant and N_c classes (Looney C. G., 1997, p. 101). For a small number of classes twice the number of nodes as there are classes can be sufficient (Looney C., 1997); however, selecting an ideal number frequently involves testing multiple architectures.

Differing opinions exist on the appropriate number of hidden layers. Although, theoretically, one hidden layer is sufficient for properly posed problems (Kurkova, 1992) complicated problems may best be solved with multiple hidden layers (Zhang G. P., 2007; LeCun, Bengio, & Hinton, 2015). Thus it is advisable to begin with a single layer and only add additional layers (complexity and computation time) if needed.

Table 2. Example philosophies on data splitting for ANNs

Reference	Training	Test	Validation
(Poh, 1991)	65%	10%	25%
(Looney C., 1997)	60%	15%	25%
(Wu, May, Dandy, & Maier, 2012)	60%	20%	20%
(Balbin, Safieva, & Lomakina, 2009)	varies	varies	10%

Figure 5. Example of Overfitting from (Bihl, 2015) using the Three-Class Insect Dataset of (Lindsey, Herzberg, & Watts, 1987) (Hand, Daly, McConway, Lunn, & Ostrowski, 1993) with an LVQ ANN

Training Method

Determining weights for a given network involves training on a dataset; two main paradigms exist in this process: supervised (classification/prediction) and unsupervised (clustering) learning (Haykin, 1999). Both supervised and unsupervised schemes are iterative, with weights updated after investigating all observations in the training set. While the learning algorithm investigates all samples, known as an epoch, statistical information is collected, such as mean squared error (MSE), in order to adjust the weights of a network.

Table 3. Common ANN training methods

Training Method	Reference for Additional Information
Back-propagation	(Rumelhart & McClelland, 1986)
Batch training	(Duda, Hart, & Stork, 2001)
Conjugate gradient	(Looney C., 1997)
Gradient descent	(Looney C., 1997)
Levenberg-Marquardt	(Levenberg, 1944)

Various strategies exist to train ANNs, Table 3, with back-propagation being one of the most popular training practices (Rumelhart & McClelland, 1986). Back-propagation assigns error through the network to each neuron, and then it adjusts the neurons that account for more error more aggressively than other neurons with the process iterating to minimize a cost function, such as MSE, or until a maximum epoch point is reached.

Recommended ANN Procedure

For best results, experimental procedures are still required to determine the optimal number of neurons, hidden layers, architecture, training settings, and data splitting scheme. Finding the ‘right’ parameters for an ANN is important for robustness. A generalized procedure widely used in practice, is shown in Figure 6 and described further in (Young W., 2010). Additionally, design of experiments approaches have also been proposed (Chiu, Cook, Pignatiello, & Whittaker, 1997) to determine optimal ANN settings. In general, three phases, including data pre-processing, training, and testing, are considered.

Figure 6. Procedural flow for ANN training (Young, Holland, & Weckman, 2008)

Example Business ANN Analysis Using JMP13

For an example analysis, bank marketing buyer analysis data from (Moro, Cortez, & Rita, 2014) will be used. Here, 20 input variables are considered with an output binary variable Y determining if the client subscribed to a long term deposit (“yes”) or not (“no”). As described in (Moro, Cortez, & Rita, 2014), the 20 X variables include numeric and categorical information, including demographics, credit, type and frequency of contact between bank and client, and external market data.

For example, ANN analysis, the Neural Network toolbox of JMP13 Pro (SAS Inc.) will be used for one example iteration of the process in Figure 6. For analysis, one selects the Y variable as the response and all other columns as the *Factors*. Settings were specified as described above with 20% of the data sequestered for validation, $N_{Hidden} = 4$ based on $a = 2$, hyperbolic tangential nodes, and one hidden layer.

Results, seen in Figure 8, mirror those of (Moro, Cortez, & Rita, 2014) where the training/testing accuracy and validation accuracy are similar with receiver operating characteristic (ROC) curve AUCs being 0.941, thus indicating that the data is effectively modeled through the ANN and accurate when predicting the response of future customers.

APPLICATIONS OF ANNs IN BUSINESS

Domains

A variety of business domains employ ANNs as the authors noted and listed in (Young, Bihl, & Weckman, 2014); the authors present Table 4 as an update on their prior work where only selected references since 2014 are included. Incidentally, ANNs are not universally employed across business domains. Some domains, such as fashion,

Figure 7. JMP13 Neural Network Setup and Initialization

require very fast response times and offer short; therefore, ANNs are largely unexplored in this area (Nenni, Giustiniano, & Pirolo, 2013).

Big Data Implications

Training of an ANN is computational demanding; however, once trained, the underlying ANN model is not computationally costly to use. When analyzing 'Big Data,' many challenges exist as documented by the authors in (Bihl, Young, & Weckman, 2015). As a strategy, developing ANNs on a subset of the data and then retraining the model as needed would be beneficial. Additionally, many large datasets contain more features than necessary and non-salient features can degrade performance; thus, feature selection and dimensionality reduction analysis (DRA) are needed

Table 4. Recent applications of ANN for business purposes

to make quality ANNs. DRA methods include input reduction methods (sensitivity, correlation studies, etc.) (Young W., Weckman, Thompson, & Brown, 2008; Hernandez, Nesic, Weckman, & Ghai, 2006; Bihl, Bauer, & Temple, 2016), and ANN-based feature screening methods (Bauer, Alsing, & Greene, 2000; Verikas & Bacauskiene, 2002), to find a parsimonious set of features.

Small Data Implications

Limited, or scarce, data is also a serious problem that often impedes the development of efficient ANNs due to ANN training procedures requiring the partitioning of data into subsets to prevent over-fitting (Porter, et al., 2001). Since the cross-validation dataset acts as an additional testing set, some researchers cannot afford to hold out a separate independent testing set (Lendassea, Simonb, Wertzc, & Verleysen, 2005).

Figure 8. ANN results using JMP13

Based on these training and data partitioning philosophies utilized within the application of ANN design, larger datasets are at times more idea than smaller ones. However, issues exist when small datasets or imbalanced datasets are analyzed. To overcome these limitation, some methods do exist such as under-sampling, over-sampling and artificial sampling methods. Over-sampling, or boosting, is a simple or naïve strategy that simply reproduces sampled data to improve the predictive accuracy of ANN when sample sizes are small (Seiffert & et al., 2008).

Under-sampling, involves making the training data groups as equal as possible to avoid biasing (Seiffert & et al., 2008). Artificial sampling provides uses real sample information to create additional synthetic samples to increase sample size for training (Bui, 2004). While all strategies have been utilized successfully in practice, 1) more research is needed for robust comparisons and 2) simpler methods, such as under-sampling, perform very well in practice when compared to more complicated methods (Seiffert & et al., 2008; Long & Servedio, 2010).

Knowledge Extraction

Practitioners employ the KDD process for a variety of reasons; one being to understand complex systems better (Browne, et al., 2003). Knowledge extraction (KE) techniques are often applied to mathematical models in order to gain insight. ANNs, though powerful in their prediction and applicability, are still viewed today as black-box model (Lek & Guegan, 1999). To eliminate the black-box mentality, three classification approaches are used to extract knowledge from an ANN. These methods include decomposition, pedagogical, and eclectic methods.

Decomposition methods use the internal structure of the ANN architecture to derive a primitive form of KE. One technique used to inspect a network's activity visually is the NID, as seen in Figure 3 (Özesmi & Özesmi, 1999). Pedagogical methods do not use the internal structure to derive or extract knowledge from a network. Instead, pedagogical methods use the network's map of input to output relationships and reformulate the relationships via another representation, e.g. decision trees (Schmitz, Aldrich, & Gouws, 1999; Young W., Weckman, Hari, Whiting II, & Snow, 2012). Finally, eclectic methods utilize a collection of decomposition and pedagogical methods, as seen in Validity Interval Analysis (VIA) method (Thrun, 1995).

Deep Learning ANNs

Deep learning methods employ multiple layers that aim to model high-level abstractions (LeCun, Bengio, & Hinton, 2015). Deep learning ANNs employ a variety of ANN variants to learn highly complex and abstract patterns, such as search engine queries and ideal responses (LeCun, Bengio, & Hinton, 2015). However, despite the many advantages of deep learning ANNs, issues can exist in their unchecked development. One example is the failure (unwarranted associations) of Google's

Photo App whereby it tagged black people as "gorillas" (Tramer & et al., 2015) (Guynn, 2015). However, it should be noted, that these issues could manifest in any pattern recognition algorithm due to biases and limitations in the data, see (Dreyfus & Dreyfus, 1992).

CONCLUSION

The authors presented a brief primer on ANNs, which summarizes issues related to ANN background, architecture selection, model building, applications, and example implementation. Since publishing an earlier version of this paper (Young, Bihl, & Weckman, 2014), ANNs have increased in business applications, but are still not as well received as simpler methods, e.g. (Nenni, Giustiniano, & Pirolo, 2013).

FUTURE RESEARCH DIRECTIONS

Another emerging direction is the use of deep learning; however, issues with deep learning show that it is not a solution to all problems. It should be noted that additional reading has been provided in Table 4, which provides a brief summary listing of business disciplines. Additionally, readers are directed to summary papers by Li (1994), Wong et al. (1997), Vellido et al. (1999), Smith and Gupta (Smith & Gupta, 2000), Haikmpoor et al. (2011), and Tkáč and Verner (2016), as extended reviews of ANN applications in business.

KEY TERMS AND DEFINITIONS

Back-Propagation: A supervised learning method used to determine the weights of an ANN, where the difference between the desired and the model's output is minimized.

Epoch: The representation of an entire training set of sample data through the learning algorithm so that an ANN's weights can be determined.

Knowledge Extraction: The process of discovering how input attributes are used within an ANN to formulate the output such that one can validate functional relationships within the model.

Neuron: An individual building block of an ANN in which weighted input values are transformed via a transfer function into an output, which is typically passed to other portions of the network.

Over-Fitting: Occurs when a mathematical model describes random error or noise instead of the real underlying relationships within a dataset, which artificially produces desirable goodness of fit metrics for training data, but produces poor metrics for testing data.

Post-Processing: A process of utilizing a trained mathematical model in order to improve the understanding of the database that has been modeled.

Pre-Processing: A process of preparing a dataset in order to develop a mathematical model.

Supervised Learning: A learning strategy in which the desired output, or dependent attribute, is known.

Unsupervised Learning: A learning strategy in which the desired output, or dependent attribute, is unknown.

Recurrent Neural Networks for Predicting Mobile Device State

INTRODUCTION

Smartphones have become a key part of everyday life as an essential tool for their users. People have fully integrated mobile devices into their lives by using them to communicate with friends, check e-mails, play games, record physical activities and take pictures, among other possible uses. Moreover, smartphones are equipped with several features (WiFi, GPS, and Bluetooth among others) that can record activities and contextual information, such as location, application usage, and even messaging and calling behaviour. Hence, smartphones are interesting options for tracking and mining user behaviour in daily life (Do and Gatica-Perez, 2014). This information offers new opportunities to analyse human behaviour aiming at enhancing the user experience with mobile devices and, at the same time, helping to ease the use of smartphones' services (Rios et al., 2014).

Several domains leverage on the prediction of mobile devices' states (Pejovic and Musolesi, 2015; Niroshinie et al., 2013; Ravi et al., 2008). For example, in the development of context aware applications, the predictions could be useful for determining the context in which applications

are running. Such context aware applications are encompassed in a concept called "Anticipatory Mobile Computing" (AMC) (Pejovic and Musolesi, 2015). The goal of AMC is deciding which actions should be taken based on predicted future states to improve the outcome. AMC concepts are present in personal assistance technology (such as Google Now, Microsoft Cortana or Siri), healthcare applications and smart cities. Personal assistance technology uses state prediction to provide relevant information to the user before such information is requested. For example, predicting that the hour in which the user goes to work allows personal assistance technology to provide information about traffic and weather, which might be relevant to the user.

Other use of predictions can be found in mobile cloud computing (Niroshinie et al., 2013). One of its key proposals is moving computing from mobile devices to the cloud to reduce battery consumption. However, to effectively reduce battery consumption, it is necessary to predict whether the energy requirements for communicating are lower than those of processing. In addition, if the mobile device is not going to be connected to the Internet when the cloud finishes its work,

computation results will be unavailable. This might lead to the repetition of the computation in the mobile device, which would waste more energy than if the mobile device had performed the computation in the first place. These are just a few examples of the developing mobile device state prediction techniques' importance.

The current state of mobile devices can be regarded as the consequence of the previous states. Consequently, future behaviour can be predicted based on how a user has been using his/her device. The generation of predictive models of human behaviour has emerged as a topic of interest in several areas, such as recommendation systems, context-aware services, and personalised and adaptive interfaces. For example, several studies have focused on predicting the probability of users to be at a particular place at a given time. Also, Do and Gatica-Perez (2014) and Liao et al. (2012) aimed at predicting which application the user will use next based on contextual information to reduce the time users spend on searching for a specific application.

Although mobile devices constantly evolve as they provide increasing functionality due to the improvements in processing power, storage capabilities, graphics and connectivity; battery capacities do not experience the same growth (Ravi et al., 2008). Power emerges as a critical resource for battery-powered systems as mobile devices. Hence, battery management becomes a crucial requirement to users. Providing battery management information requires the ability to accurately predict remaining battery life in a dynamically changing system. Interestingly, most of the studies in the literature focus on offering location prediction, or application personalisation, instead of analysing the impact of user behaviour in battery level and life. In this context, this work evaluates the suitability of Recurrent Neural Networks (RNN) for predicting future battery levels of mobile devices based on the users' usage pattern of different features, such as the WiFi connection or screen status, among others.

BACKGROUND

The analysis of human behaviour through smartphone usage has attracted considerable interest in recent years. Works on smartphone mining include physical activity recognition by applying learning techniques to accelerometer data, and personalisation of content and user interface. For example, Do and Gatica-Perez (2014) predicted human behaviour based on smartphone sensors using statistical methods commonly used in signal processing for forecasting time series. Particularly, user location within a ten-minute window was predicted along with the applications users were more likely to use based on the location, time, Bluetooth proximity and communication logs. The approach linearly combined least-squares linear regression, logistic regression and Markov models. Location prediction results showed that the most important predictors were Bluetooth proximity, location and time, and confirmed the dependency between human mobility and social interactions.

Application usage prediction was also studied in (Shin et al., 2012; Liao et al., 2012). Both approaches aimed at presenting users with the most probable applications to be used aiming at reducing the time spent searching for a desired application. Shin et al. (2012) based the prediction on a probabilistic Naïve Bayes model that was personalised to each user according to his/her application usage pattern. Prediction was based on information from GPS, cellular network, accelerometer, calls, WiFi, Bluetooth, screen status, battery status, illumination and running applications. Results showed that the previously used applications, location and hour of day were useful predictors.

Liao et al. (2012) created temporal profiles of application usage and proposed a three step probability-based scoring model to compute the probability of using an application. First, the periodicity of application usage was detected by a Discrete Fourier Transform. Second, captured periodicities were hierarchically clustered to

identify users' behaviour. Clusters represented different usage patterns. For example, one cluster corresponded to weekday behaviour, whereas other comprised weekend behaviour. Finally, the possible application usages were predicted based on the Chebyshev's inequality.

Regarding connectivity prediction, Rios et al. (2014) aimed at predicting Bluetooth and WiFi usage based on mining association rules from information regarding data, WiFi and Bluetooth connections, GPS status changes, ringer status (silent, vibrate, normal) changes and headset connection. The rules were able to accurately capture the relations between WiFi connection habits relative to location and GPS status. The authors highlighted the potential of their approach for assisting users in the activation/deactivation of connectivity features to increase battery life.

Finally, closely related to this work are the studies carried out in (Wen et al., 2003; Ravi et al., 2008), which aimed at predicting battery life. Wen et al. (2003) predicted battery based on information regarding variations in workload, application usage, battery charge rates, the charging-cycle effect and a voltage curve. Then, such information was combined into an online linear curve fitting statistical approach. Ravi et al. (2008) also aimed at predicting the next charging opportunity, call time predictor (i.e. how much call-time will the user require over a determined time period), and application battery consumption. With such information the authors intended to inform users not only when they will run out of battery, but also, which applications should they terminate to increase battery life. The analysis considered location, battery status, list of running processes, id of the cell the smartphone is connected to, past calling behaviour, average number of minutes of call time that users need during each hour of the day separated between weekdays and weekends, and the base curve of battery life.

PREDICTING MOBILE DEVICES STATES USING RNN

This work aims at predicting a mobile device future state based on previous states, i.e. predicting sequences of states. Mobile device state changes as the result of an event in time. For example, a change in the battery level can be defined as an event, which triggers a new state of the mobile device in which the battery level is modified, and all other features remain the same. Particularly, this work defines a state as a combination of the following features:

- **Time Between Events:** Minutes passed in-between the current state and the previous one. Type: Integer.
- **Battery Level:** Mobile device current battery level ranging between 0 and 100. Type: Integer.
- **External Energy Supply:** Whether the mobile device is plugged to an external energy supply, e.g. AC adapter or USB connection. Type: Boolean.
- **Screen On/Off:** Whether the mobile device screen is active. Type: Boolean.
- **WiFi:** Whether the mobile device is connected to a WiFi network. Type: Boolean.

To predict future states, RNN will be used. RNN (Williams and Zipser, 1989) differ from feed-forward Artificial Neural Networks (ANN) in that they can have cycles in the computational networks. These cycles allow the network to have dynamic contextual windows, instead of fixed size windows like the standard feed forward models. This dynamic window contributes to the enormous potential of RNN for successfully predicting sequences of events. In this context, the sequence of events models the sequence of states for a mobile device. Although this work does not evaluate the

feasibility of deploying the proposed predictor in a mobile device, a work (Alsharif et al., 2015) on decoding keyboard gesture patterns into text by means of an RNN shows that it is possible to use RNN within a mobile device.

SOLUTIONS AND RECOMMENDATIONS

The proposed ANN is based on the RNN known as Long Short-Term Memory (LSTM) (Hochreiter and Schmidhuber, 1997). RNN were used because they are very effective for predicting sequences (Alsharif et al., 2015) as new predictions depends on past predictions. This allows to use an arbitrary number of previously known states to make a prediction.

The proposed ANN needs at least two consecutive states for predicting the following state. Figure 1 depicts the architectural structure of the

ANN. In a first step, each state is processed by a multi-layer perceptron (MLP). Each layer linearly combines its input vector using a weighting matrix (W) and an internal bias (B), with the combination being processed via

$$L_n(i) = \tanh\left(\left(i_n^T W_n\right)^T + B_n\right),$$

which describes how each layer behaves. Note that functions such as $\tanh$ and sigmoid are applied element wise to the vectors. Then, the different layers are combined in a MLP via

$$L_n\left(L_{n-1}\left(\dots L_1(x)\dots\right)\right).$$

As a result of these operations, the newly computed vector can be used as input for another layer.

Since the proposed ANN uses two different MLP for processing the two states, the results

Figure 1. Neural Network structure

of each MLP need to be combined. For this, the proposed approach uses a layer similar to the layers in MLP, but that accepts several inputs. In the approach this layer is called Join Layer ($JL(i..j)$), which can be defined as

$$\tanh\left(\left(i_n^T W_{JL-i} + \dots + j_n^T W_{JL-j}\right)^T + B_{JL}\right)$$

The Join Layer result is fed to the recurrent layer of the ANN, namely the LSTM layer. This layer is recurrent because it has two variables that take their values from previous outputs: the context and the hidden state. Since the output of this layer depends on previous outputs, the prediction of the proposed ANN depends on previous predictions making it an RNN. The context (c_{t-1}) is the LSTM layer previous output, and the hidden state (s_{t-1}) is the LSTM layer previous internal state. For the first prediction, the context c_0 and the hidden state s_0 are vectors full of zeros. The LSTM layer has three inputs: the current state (x_t), the hidden state and the context. The hidden state s_t depends on s_{t-1} , $g_t(x_t, c_{t-1})$ and $y_t^{in}(x_t, c_{t-1})$, and can be defined as

$$s_t = s_{t-1} + g_t(x_t, c_{t-1}) \circ y_t^{in}(x_t, c_{t-1}),$$

where

$$g_t(x_t, c_{t-1}) = \text{sigmoid}\left(\left(x_t^T W_g^x + c_{t-1}^T W_g^c\right)^T + B_g\right)$$

and

$$y_t^{in}(x_t, c_{t-1}) = \text{sigmoid}\left(\left(x_t^T W_{y^{in}}^x + c_{t-1}^T W_{y^{in}}^c\right)^T + B_{y^{in}}\right).$$

After computing the new hidden state, the LSTM layer output (c_t) can be defined as the dot product $h_t \circ y_t^{out}(x_t, c_{t-1})$, which takes as input

$$h_t = \text{sigmoid}\left(\left(s_t^T W_h\right)^T + B_h\right),$$

and

$$y_t^{out}(x_t, c_{t-1}) = \tanh\left(\left(x_t^T W_{y^{out}}^x + c_{t-1}^T W_{y^{out}}^c\right)^T + B_{y^{out}}\right).$$

Finally, the LSTM layer output is taken as input by other MLP for obtaining the final prediction.

In order to be analysed by the NN, mobile device state features were encoded into a vector of elements, in which each element can adopt either -1 or 1. The selection of such values corresponds to the fact that ANN usually rely on $\text{sigmoid}(i)$ and $\tanh(i)$ functions, which when applied to -1 or 1 result in values close to their asymptotes. Also, applying such functions to 0 results in the mean value of their asymptotes. For example, $\tanh(i)$ has two asymptotes: -1 when $i \rightarrow -\infty$ and 1 when $i \rightarrow \infty$. Applying the function to the selected values results in: $\tanh(-1) \cong -0.7616$, $\tanh(1) \cong 0.7616$, while $\tanh(0) = 0$, i.e. the mean value of the asymptotes. Integer features were encoded using their binary representation. For instance, the “Hour of the day” feature was encoded using the five binary digits needed for representing any number between 0 and $31 = 2^5 - 1$. In the case of the “Time between events” feature, the maximum time was set to 3 hours or 180 minutes. Thus, it was encoded using 8 elements. Finally, for binary features, -1 stands for false, and 1 stands for true, e.g. when the mobile device is connected to a WiFi network the “WiFi” feature is 1, otherwise it is -1.

Figure 2 illustrates the application of the approach for predicting the states from time $n+1$ to m using the previous n states. In a first step, the ANN is fed with the known states x_1 and x_2 resulting in a prediction x_3' . Such step is not performed for obtaining the prediction, as x_3 is known, but for the sake of the ANN internal state. After this step, the ANN is fed with x_2 and x_3 . The ANN is fed repeatedly with the known states until the x_{n+1}' prediction is obtained. At this moment, as no states are known, x_{n+1}' is the first state to be predicted. Unlike the input, in which each element can only adopt two values, the output elements adopt ap-

proximations to the expected values. For instance, if a particular element of x'_{n+1} , is -0.9 it is likely that the real value of x_{n+1} is -1. Hence, x'_{n+1} needs to be pre-processed before it is fed to the ANN. Eq. 1 shows the pre-process function. The sequence prediction algorithm has been proved to be effective in other sequence prediction domains (Sutskever et al., 2014).

$$p(x') = \begin{cases} 1 & x' \leq 0 \\ -1 & \text{otherwise} \end{cases}$$

Experimental Settings

The dataset used in the experimental evaluation was gathered from a mobile device using the application described in (Rios et al., 2014). The mobile device owner was a University employee who volunteer for the study. The mobile device was a Samsung Galaxy SII and the dataset was collected between 5th of June of 2015 and 8th of October of 2015. Since the mobile device owner could turn on and off the logging application at will, the dataset does not have information for every day between those dates. The resulting dataset comprises data belonging to 19,067 records of mobile device states collected during 79 days. Records were grouped into chunks, where each chunk contains states from a single day. However, days in which states were separated by more than 3 hours were split into several chunks. In total, 83 chunks were created, which were split into training and validation splits. The training split comprised 70% of the chunks, which were randomly selected. Table 1 summarises the dataset characteristics.

Table 1. Dataset description

	Full Dataset	Training Split	Validation Split
Days	79	56	23
Chunks	83	59	24
Events	19,067	12,809	6,258
Average	230	217	261
St. Dev.	168	124	246
Min. Size	63	63	75
Max. Size	979	638	979

The proposed ANN has 546,862 trainable parameters, which are denoted by the weights matrices (W), and the biases vectors (B) denote the ANN parameters to be trained. Table 2 shows the size of the matrices and vectors involved in each of the first MLPs. The parameters of the join layer and LSTM are detailed in Table 3 and Table 4, respectively. Finally, the parameters of the MLP that produces the final prediction are presented in Table 5.

To fit the ANN parameters, different approaches were evaluated. Firstly, two error functions were considered, namely Mean Squared Error (MSE) and Cross-Entropy Error (CEE). MSE consists in adding the element wise squared difference between the expected value and the predicted value, as shown in Eq. 2 CEE is used in logistic regression and represents the entropy between the obtained prediction and the expected value. For the expected values being $y \in \{0,1\}$, Eq. 3 presents the cross entropy formula. Since the elements of the expected values are $y_i \in \{0,1\}$, the correction formula $c(x) = (x+1)/2$ was applied element wise

for both expected values and predictions before computing the Cross Entropy Error.

$$J(y, y') = \frac{\sum (y_i - y'_i)^2}{N}$$

$$J(y, y') = \frac{-\sum (y_i \cdot \log(y'_i) + (1 - y_i) \cdot \log(1 - y'_i))}{N}$$

To avoid overfitting, the impact of adding a regularisation factor to both MSE and CEE was also assessed. The regularisation factor was calculated as the sum of the parameters' L_1 -norm. Finally, two different techniques were evaluated to approximate the ANN parameters. The first one was the well-known Stochastic Gradient Descent. The second one was ADADELTA (Zeiler, 2012), a variation of Stochastic Gradient Descent in which the learning rate is computed based on the historic values of the gradient. The two error functions,

regularised or not, and the techniques for fitting parameters can be freely combined resulting in eight different settings.

Experimental Results

The first experiment aimed at assessing all potential training settings described above. For each setting, the evolution of the ANN up to 50 epochs was evaluated. One-state-in-the-future prediction stands for predicting the state x'_{n+1} using all the states between x_1 and x_n . Since the ANN requires at least two previous states for generating a prediction, the first possible prediction is x'_3 using x_1 and x_2 . In a chunk of m states, the last prediction is x'_m using $(x_1, x_2, \dots, x_{m-1})$.

Firstly, the training dataset was evaluated using MSE, as shown in Figure 3. Within this figure, Figure 3a and Figure 3b present the errors obtained when training the ANN using MSE or CEE, respectively. The settings using Gradient Descent and MSE achieved the lowest errors. Furthermore, the setting without regularisation performed slightly better, which is expected as regularisation is intended to reduce overfitting the training dataset. However, these results alone are not sufficient for evaluating as overfitting is not completely avoided. Hence, the same evaluation was performed using the validation dataset. Figure 4 shows the results for the validation dataset. Particularly, Figure 4a shows the errors for the ANN trained using MSE, and Figure 4b shows the errors for ANN trained using CEE. As expected, the obtained MSE are higher than the errors obtained for the trained dataset. The shape of the curves in Figure 4a and Figure 4b are similar to the ones in Figure 3a and Figure 3b, respectively. This implies that the ANN did not overfit the training data. Moreover, Gradient Descent and MSE without regularisation also achieved the lowest error.

The second experiment was designed for evaluating the sequence prediction capabilities of the ANN. Thus, predictions of up to 10 states

into the future were generated using the validation dataset and the best performing ANN from the previous experiment. Such ANN was the one obtained after the 34th epoch using Gradient Descent and MSE without regularisation. Note that for predicting the n state into the future, the $n-1$ previous predictions were used. For instance, suppose that m states are known and that the state $m+n$ is to be predicted. In this context, the ANN would use as input the following state sequence

$$(x_1, \dots, x_m, p(x'_{m+1}), \dots, p(x'_{m+n-1})).$$

The average time between 10 states is 48'26.82" with a standard deviation of 58'47.27". The minimum registered time between 10 states was 10 minutes and the maximum was 697 minutes.

For the integer type features, namely "Hour", "Time between events", and "Battery", the error was calculated as the Mean Absolute Error (MAE) as defined in Eq. 4. Figure 5 presents the obtained MAE. For "Hour" and "Battery", the MAE increases as the number of states in the future increases, whereas for "Time between events" remains invariant. This is expected due to the fact that "Hour" and "Battery" values are correlative with previous values, while "Time between events" values are not. For instance, if "Battery" has a value of 60% and the battery is not in charging state, it is very unlikely that the next state has a value for "Battery" of 10% or 90%. Hence, an error predicting a "Battery" value would have a heavy impact on further predictions.

$$MAE = \frac{\sum |expected\ value - predicted\ value|}{\# prediction}$$

Since the error in predicting the time between n states is given by the sum of each individual prediction error for "Time between events", the mean accumulated absolute error (MAAE) is defined in Eq. 5. MAAE accounts for the accumulated error in a prediction sequence. In this context, the MAAE for "Time between events"

Figure 3. MSE for training dataset

was 121 minutes. Considering these results, it can be concluded that the ANN did not performed effectively for predicting “Time between events”, but performed with a low error rate for predicting “Hour” and “Battery”.

$$MAAE = \frac{\sum_{i=1}^N |expected\ value_i - predicted\ value_i|}{\# prediction}$$

The relation between the “Hour” and “Battery” features’ Absolute Error (AE) and the “Time between events” feature Accumulated Absolute Error (AAE) for the 10-state-in-the-future prediction was studied to determine whether failing at

predicting the “Time between events” is correlated to errors in the prediction of other features. Table 6 presents the Pearson correlation between “Hour” and “Battery” features’ AE, and the “Time between events” feature AAE. There is a strong correlation between the errors of predicting “Hour” and “Time between events” probably because both are related to the prediction of the time between states. However, there is no strong correlation with the “Battery” prediction, i.e. errors in “Battery” prediction are independent from errors in the time interval prediction.

Finally, a True Positive (TP) and True Negative (TN) analysis for the prediction of the binary fea-

Figure 4. MSE for validation dataset

Figure 5. Mean Absolute Error up to 10-state-in-the-future prediction

Table 6. Pearson correlations with “Time between events”

Feature	Correlation	p-value
Hour	0.400	>0.001
Battery	0.005	0.719

tures (“External Energy Supply”, “Screen on/off” and “WiFi”) was performed, as Figure 6 reports. The best results were obtained when predicting “External Energy Supply”. Although the TP and TN decrease as more states into the future are predicted, they are never below 80% and 95%, respectively. The ANN also achieved good performance when predicting the “WiFi” feature with a TP rate of 70% and a TN rate of 80%. However, predicting the “Screen on/off” feature resulted in low TP and TN rates. Although the performance when predicting this feature was relatively good when considering a 1-state-in-the-future prediction, it rapidly decreased as more predictions into the future were performed. For example, predicting that the screen would be on in the second future state provided no real information about whether the screen would be on or off, as the TP rate was about 50%. Furthermore, after three states into the future, predicting that the screen would be on

meant that the screen would be most likely off. This was probably a result of a lack of information about user incentive for activating the screen, such as application notifications or user location.

FUTURE RESEARCH DIRECTIONS

Since this paper defines mobile device states using only a small subset of all the possible features, future studies will consider additional features, such as location, Bluetooth connection, incoming/outgoing calls, cellular connection, or 3G signal strength. The main limitation of the current approach is the high number of parameters. Future research should evaluate other ANN configurations with fewer parameters.

Future works will further validate the proposed approach using a larger dataset, such as the Cambridge Device Analyser dataset (Wagner et al., 2014). Additionally, the possibility of using just one ANN for modelling a number of users could be studied. This could be useful in domains in which group behaviour is more important than individual behaviour. Another line of work is comparing ANN based state prediction with other machine learnings techniques. Finally, more complex

Figure 6. True-Positive/True-negative analysis

ANN models should be evaluated in the future. Such models would not only include other type of ANN layers, but also expand the definition of the mobile device state by adding other features, such as location, CPU usage, and day of the week.

CONCLUSION

This study aimed at evaluating the suitability of ANN for predicting mobile device future states. The obtained evidence suggests that RNN have potential for predicting future states of mobile devices. However, the results were mixed, as the ANN was able to effectively predict with low error rates the state of features, such as “Battery” or “External Energy Supply”, while it was ineffective for predicting other features, such as “Screen on/off” or “Time between events”.

KEY TERMS AND DEFINITIONS

Artificial Neural Network: A kind of machine learning algorithms loosely based on how biological neural networks work.

Epoch: A single training pass through the entire training set.

Error Function: A function used for assessing how well a machine learning method performs.

Gradient Descent: Technique for fitting parameters of a function.

Mobile Device: A computational device that people carries, such as smartphones or tables.

Mobile Device State: A set of variables that describe the mobile device's current conditions.

Recurrent Neural Network: ANN that uses previous states for making new predictions.

INTRODUCTION

The initial theory of Visible Light Communication (VLC) was founded in the 1880s when Alexander Graham Bell invented the photo-phone which was used to transmit a voice signal using the modulated sunlight. Since the time of Graham Bell, optical communication research has attracted the interest of scholars around the world and has evolved into a new IEEE standard namely the P802.15.7 - Standard for Short-Range Wireless Optical Communication (standard, 802.15.7 (2015)). In 2003 at the Nakagawa Laboratory in Keio University, Japan, they have proposed using the Light Emitting Diodes (LEDs) for data transmission.

A major factor that contributes to the evolution of VLC technology is the existing infrastructure. Hence, previously installed facilities, such as LED traffic lights or LED sign boards are readily used. Since the transmitters for VLC are light sources, they function for lighting purposes and illuminate the surrounding environment, hence the radiation power and signal-to-noise ratio (SNR) is high; paving the way for a stable communication link (T. Yamazato, I. H. (2014)).

With respect to the emergence of green communication, VLC is highly energy efficient as it utilizes LEDs. The United States Department of

Energy further corroborated the importance of LED technology, as shown in Table 1. There is superiority in terms of power consumption and operating lifetime in LED technology as compared to traditional lighting technology, such as incandescent and fluorescent lighting. This clearly shows the potential of the LED lighting technology to replace all the conventional illumination tools as well as serve as a reliable transmitter for a VLC link (Chung, Y.-Y. T.-Y. (2014)).

Radio Frequency (RF) wireless connectivity has been used for several decades as it allows for indoor and short distance links to be established without any physical connection. However, these solutions remain relatively expensive and have low to medium data rates. RF wireless links require that spectrum licensing fees are paid to federal regulatory bodies and are required to be contained within strict spectral zones. These frequency allocations are determined by local authorities and may vary from country to country, making a standard interface difficult. Since the visible light spectrum is not in the licensed band (400 to 790 THz), licensing fees can be avoided which effectively reduces system cost. In addition, the broadcast nature of the RF link is beneficial for mobile connectivity but this may result in interference between devices located within close prox-

Table 1. Performance of the conventional and LED lighting technology

Lamp Type	Watts	Lumens	Operating Lifetime
Incandescent	60	900	1000
Compact florescent lamp	15	900	8500
LED (2011)	12.5	800	25000
LED – future(2015)	5.8	800	40000

imity. Due to the RF wavelength, it is difficult to contain within boundaries and can impede system performance (Hranilovic, S. (2005)).

Optical radiation in the infrared or visible range is easily contained by opaque boundaries. As a result, interference between adjacent devices can be minimized easily and economically. Additionally, inexpensive LEDs and photodiodes are able to interchangeably work between baseband and transmission frequencies where as high-frequency RF circuit design techniques are required in the RF domain. Free-space optical (FSO) links with an inherent low probability of intercept and anti-jamming characteristics is among the most secure of all wide-area connectivity solutions (Hranilovic, S. (2005)).

Unlike many RF systems that radiate signals in all directions, thus making the signal available to all within the receiving range, FSO transceivers use a highly directional and cone-shaped beam with a dominant line-of-sight (LOS) propagation path. Therefore, interception is extraordinarily difficult and anyone tapping into the systems can easily be detected as the intercept equipment must be placed within the very narrow optical foot print (Ghassemlooy, Z., P. W. (2012)). Although this contributes to the security of wireless optical links and reduces interference it also greatly impacts the high mobility of such devices.

The aim of this book chapter is to introduce the concept of VLC as an emerging technology from a system and hardware design point of view, and shed the light on the rich features and potential of this technology that make it a viable substitution for other wireless technologies. The importance of

this technology will be demonstrated by covering various applications and scenarios.

BACKGROUND

VLC is the process of transmitting digital data by using the visible light spectrum. This can be achieved by modulating the data using a light source such as LEDs that can be switched fast enough to avoid observable flickering or light dimming, another possible way is to change the light intensity in a way that is not observable to the human eye but can be detected using an appropriate sensor such as a photo diode (PD). Along with its prime function of lighting, LEDs can also serve to transmit data as long as there are suitable receivers.

Additionally, image sensor pixels can be used as an effective VLC receiver. The ability to spatially separate multiple sources of image sensors provide an attractive feature to VLC. Image sensor pixels can sense LED transmission sources and discards other pixels which detects ambient noise. More specifically, outdoor usage of VLC is possible by discarding pixels associated with noise sources such as the sunlight or streetlights. Hence, image sensor based VLC is an attractive solution for outdoor mobile applications (T. Yamazato, I. H. (2014)). With regards to short-range VLC applications, the SNR of a direct detection receiver is proportional to the square of the received optical power. Therefore, VLC links can tolerate only a comparatively limited amount of signal path loss.

Figure 1 shows a general block diagram for a simple VLC transceiver. As shown in the figure,

the upper part represents the transmitter, where binary data is first passed to a coder such as a Reed-Solomon coder (Khalifeh, A. Y. (2010)) where error correction codes are added. After that, binary data is modulated using a digital modulation scheme such as binary On-Off Keying (OOK) where data is modulated by passing it to an amplification circuit that drives an LED(s), which converts the data into light over the wireless communication channel.

One can notice from Figure 2 that either a single or several LEDs can be used to transmit data. The same applies to the receiving circuit, thus four different configurations can be used to increase transmission rates, as well as improve the received SNR; (a) Single-Input Single-Output (SISO), where only one LED transmitter and one photodiode receiver is used, (b) Single-Input Multiple-Output (SIMO), where one LED transmitter and multiple photodiode receivers are used, (c) Multiple-Input Single-Output (MISO) where multiple LED transmitters and one photodiode receiver is used, and finally, (d) Multiple-Input Multiple-Output (MIMO) where multiple LED transmitter and multiple photodiode receivers are used.

The data path is then transmitted to the receiver circuit, where the light pulses are detected by a photodiode(s). The output signal is then passed to an amplifier, pulse shaping and re-generation

blocks, a channel decoding module to correct the introduced errors, and a demodulator circuit that will detect and convert the signal back into binary data. Without any ambient noise or distortion, the transmitted bit stream should reach the destination without any errors. However, due to the internal and external noise sources, some binary data will be falsely detected which causes bit errors. In addition to the typical additive white Gaussian noise that is locally generated by the receiver electronic circuit, VLC receivers are prone to the ambient surrounding and background lights that can cause errors in the detection process.

However, in order to mitigate the effect of these external sources, various techniques are used such as the one proposed in (Ya'nez, V. T. (2009)) where the channel characteristic is estimated and the received signal is equalized based on the channel estimation model. Another technique presented in (Ya'nez, V. T. (2009)) uses the wavelength filtering to reduce the unwanted inference signal.

VLC APPLICATIONS

This section discusses in details the major applications where VLC has a great potential. Applications are divided into two main categories; indoor and outdoor. VLC can be used in various indoor

Figure 1. VLC transceiver block diagram

Figure 2. Several transmitter-receiver configurations

applications and scenarios, namely, in high-density indoor areas such as classrooms, conference halls, convention centers and other assembly spaces where light can be used to broadcast relevant information to the audience. Entertainment applications can also utilize VLC for video and audio streaming and broadcasting. Indoor navigation and localization is another important application of VLC, and finally, VLC can play an important role in data transmission in sensitive areas where radio wireless communication is not preferable, some examples are in hospitals and inside the airplanes. A closer look for these potential applications will be described next.

VLC can also be used in various environments where it is not safe or recommended to use the radio spectrum, since it may interfere with other critical electronic equipment. The other set of applications that can efficiently utilize this technology is some of the outdoor-based applications. Research has been done on the field of vehicle-to-vehicle (V2V) communications where cars can communicate with each other to exchange critical and general messages. Additionally, it can be easily used for Intelligent Transportation Systems (ITS) and vehicle-to-infrastructure and infrastructure-to-vehicle (V2I and I2V) communication.

Indoor Applications

VLC has many potential indoor applications. This is due to the fact that an indoor channel changes slowly when compared to outdoor channels, where the channel may vary more rapidly. Three main applications will be discussed: Indoor localization and positioning, medical services, and VLC in-flight communication systems.

Indoor Localization and Positioning Services

One important application of VLC is indoor localization and positioning. This is a vibrant research area that is gaining much attention recently. Positioning applications cover a wide area where the technology can be included into various consumer electronics. Indoor positioning technology can be used to guide users in large areas. Moreover, positioning systems using VLC can also detect products inside large warehouses, automating some record management processes.

As known in literature, radio signals coming from Global Positioning System (GPS) satellites cannot penetrate well through walls of large buildings, consequently, fast and accurate indoor posi-

tioning is difficult to achieve by GPS. To overcome this problem, there are two possible alternatives; RF and VLC-based techniques. Examples of RF based techniques are: wireless local area network, radio-frequency identification (RFID), cellular, ultra-wide band and Bluetooth. These technologies will have positioning accuracies from tens of centimeters to several meters. But unfortunately, this amount of accuracy is not sufficient for many indoor applications. Hence, the techniques based on VLC are gaining greater attention.

LEDs are currently being installed in many large buildings such as museums and shopping malls, because they have the advantage of much longer life and lower operating cost. For these reasons, indoor positioning techniques based on VLC and LEDs are the desirable and preferable options (LVX Minnesota lightning. (2015)).

Medical Services

Another major concern these days are regarding the compatibility of medical devices in healthcare centers with the incorporation of wireless technology (S.S. Muhlen, D. D. (2008)). RF wireless technology has always been associated with the emission of electromagnetic interference (EMI) (H. Hong, Y. R. (2008)). Intrusion of the EMI jeopardize the quality of medical monitoring, as the accuracy and efficiency of data transmission is crucial for the medical staff to provide corresponding measures or treatment, based on the real-time information received (K.S. Tan, I. H. (2001), Chung, Y.-Y. T.-Y. (2014)).

VLC can be applied to indoor medical applications by transmitting patient data as well as management data. Healthcare information such as electrocardiography (ECG), photoplethysmogram (PPG) signals and text information can be transmitted simultaneously, using a single channel VLC. This allows for a more precise and accurate monitoring and diagnosis.

VLC In-Flight Communication Systems

The use of VLC technologies for offering data networking for passengers during flight is another promising indoor application. Internet access, Wi-Fi is traditionally used to connect the passenger devices to an access point that will send their request to the internet either via a satellite connection or via plane-to-earth data link. This Wi-Fi scheme shares the radio spectrum among many passengers, which may cause congestion and reduce the speed of communication. In addition, Wi-Fi may affect the airplane navigation systems especially at take-off and landing causing EMI.

A better solution can be implemented by utilizing a hybrid radio and optical system, where passengers may use the radio spectrum for uploading their requests, which usually require less bandwidth than the downlink. The downlink can be provided to the passengers via the personal LED lights available on top of their seats. This scheme will increase the internet speed due to abundant bandwidth available in the optical domain and will reduce the interference to the airplane navigation system. Brighter overhead lighting will result in higher SNR and greater connectivity.

Outdoor Applications

In this section, potential outdoor applications for VLC will be discussed. Despite the more challenging problems such as fast time varying channels and users' high mobility, VLC, if designed properly, can be used in several outdoor applications such as automotive communication, intelligent transportation systems, and underwater communications.

Visible Light Communication in Automotive Industry

Due to VLC being optimal for short range communication, it has significant potential in the

automotive industry such as car-to-car (C2C) and Intelligent transportation systems (ITS). Additionally, existing infrastructure is in place to take advantage of VLC such as headlights and streetlights. In the next few years, the implementation of LED taillights, brake lights, will all be more than 50% (Cui, K. C. (2012)). All these conditions make it desirable to consider VLC in the automotive industry. Vehicular Visible Light Communications (V2LC) offers a dependable solution to put into operation vehicle-to-vehicle (V2V) communications and requires minimal installation cost.

V2LC is challenged by dynamic ambient noise, high mobility, and moderately low transmitter heights on communicating systems such as vehicles and roadside units. These limitations make the V2LC channel modelling a challenging task. V2LC utilizes either a photodiode detector or a camera installed on the vehicle to be used as a receiving element. It was found that V2LC systems perform better in high volume vehicular traffic; this is because of the fact that visible light can mainly propagate within proximity and LOS to reduce interference and increase link scalability (CALM. (2011)).

C2C Communication System

A traditional C2C -VLC scenario is shown in Fig. 3, where the car on the left side communicates with the car on the right side using its headlamp. As shown, the projected beam pattern is single, and the received light consist of the LOS and reflected or Non-Line of Sight (NLOS) components. It can

be noticed that a multi-path interference will occur due to the reflected rays from the road surface, which depends on many factors such as the pavement material, the angle of incidence as well as the weather condition (rain, snow, fog, etc.).

There are many regulations issued by Economic Commission of Europe and Federal Motor Vehicle Safety Standards in United State of America related to headlamps to insure that vehicles will provide good road illumination. At the same time, the light emitted from headlamps should not visually disturb other road users. Hence, the lamp, its reflective devices, and other associated equipment must achieve specific requirements. Therefore, the Lambertian model which has been used widely in indoor VLC LED modelling, cannot be used to model the vehicle's light pattern (Kumar, N., et al. (2012)).

In C2C VLC links, usually the LOS and the NLOS components form the received optical power. For FSO, there are additional noise sources, such as the background solar radiation, streetlights, vehicles, and secondary reflections which can be treated as artificial light (Ghassemlooy. Z., P. W. (2012)). The background solar radiation is mostly the dominant noise source as it is composed of direct and scattered radiation (Cui, K. C. (2012)). As such, good noise cancellation mechanisms are required to account for the nature of these noise sources.

In addition, appropriate signal processing algorithms are needed to equalize the received signal and improve its condition. Especially, the channel coherence time will be very short in an outdoor vehicular environment due to increased

Figure 3. C2C VLC and projected LOS and NLOS beam patterns

mobility of fast moving vehicles. Hence, any channel estimation and equalization has to be achieved seamlessly.

ITS Traffic Light to Car Communication

Improvements to safety, fuel consumption, and transportation time are the key objectives of an intelligent transportation system. ITS refers to the potential of adding information and smart communication technologies to the transportation infrastructure and vehicles in order to enhance transportation safety, mobility, and support productivity through the use of advanced communications technologies. VLC can play an important role in ITS, such as broadcasting important traffic information. Here several configurations, such as V2V using LED-based rear panel lights, and bidirectional infrastructure-to-vehicle are possible. Traffic information system using LED-based traffic lights were investigated by many authors. They touched upon topics such as analyzing the communication performance and defining a service area, in which communications using a particular data rate together with intensity modulation OOK can be maintained.

VLC is suitable for both a broadcast system in I2V communication systems and effective in V2V as well. In a V2V scenario, a vehicle in front of a traffic light can receive the information sent by the traffic light, and then it can relay this information using the brake lights to the vehicle running behind. This can be extended to establish a vehicle ad-hoc network. With respect to I2V broadcasting, there is no need for extra power to broadcast traffic safety related information, which can be continuously broadcasted to support smooth traffic flow as well as reducing accidents and fatalities (CALM. (2011)).

LED-based traffic lights are also considered to be a suitable choice for traffic light Road Side Units (RSUs) in the ITS architecture without the need for additional infrastructure. One of the most

possible approaches of communication between an LED-based RSU and a vehicle is presented in Fig. 4. The first stage is collecting and passing the detected information to a central control unit, which consists of many parts such as data processing, geographical distribution of the data, and information broadcasting. After the data collection stage, traffic control actions are made. Traditional ITS systems are normally based on wireless radio solutions and short range infrared systems.

In order to deliver information from the traffic control infrastructure, which is represented by traffic lights to vehicles, VLC can be effectively integrated into this scenario. This technique offers many advantages, like cost effectiveness, alleviation of additional wireless communication support, and energy efficiency. The most important benefit is that it does not require additional power to support future communication systems. Fig. 4 shows that the ITS use control technology and access networks to achieve communication facilities. In this case, it becomes important for an ITS architecture design to be flexible enough to accommodate integration of new systems (Kumar, N. L. (2012)).

Underwater Communication

Providing an efficient and reliable data transmission for underwater communication is a challenging task, this is due to the nature of water, which absorbs the energy of the transmitted signal and refracts it. Data transmission underwater suffers from high-energy consumption, long propagation delay, and limited link bandwidth. RF-based solutions are not efficient due to the high attenuation and due to the multipath signal propagation (Gabriel, C. K. (2011)). As an alternative, acoustic waves are in use for underwater communications. Table 2 compares acoustic and optical communication methods for underwater use. As shown in the table, both acoustic and optical mediums suffer from power loss. The acoustic waves suffer

Figure 4. VLC integration with ITS architecture depicting the vehicle Field-of-View (FOV) and the Variable Message System (VMS)

from more than 0.1 dB per meter per Hz, so the higher the frequency and distance, the higher the attenuation and power loss.

For optical transmission, the amount of power loss depends on the turbidity, which is a measure of the water purities and its clarity. The higher the turbidity, the higher the power loss. In addition, the signal strength is inversely proportional with the distance (Lanbo, L. S.-H. (2008)). Although acoustic transmission has a greater range, its transmission rate is very limited. While the optical communication link has higher data rates for low distance, it becomes detrimental over a long distance. The propagation delay for optical communication is much lower when compared

to an acoustic link, since light speed inside water is significantly faster than the speed of acoustic transmission. Moreover, optical transceivers are relatively cheap and less complicated when compared with acoustic transceivers. It is important to note that the performance metrics in Table 2 are based on a seawater environment, so it may vary for other underwater environments.

DISCUSSION

Ever since the growing demand and use of data, there has been a need to reliably transmit significant amounts of data in real time. Current

Table 2. Comparison between underwater communication using acoustic and optical communication methods, assuming a seawater environment

Property	Acoustic	Optical
Require alignment	No	Yes
Receiver complexity	Higher	Lower
Recommended communication range	Up to 5 km	Up to 100m
Data rate	Up to 100 Kbps	Up to 1 Gbps
Power loss	> 0.1 dB/m/Hz	proportional to water turbidity
Propagation delay /speed	large/slow (1500-2000 m/s)	low/ high (2.255×10^8)
Frequency band	~ kHz	10^{15} Hz

Sources: Lanbo, L. S.-H. (2008), Yang S., K., (2011), Lurton, X. (2010)

technology, as well as a growing number of users limit the communication capacity. Hence, there is a great need for high bandwidth, energy efficiency, cost, and reliability for a communication link. Hence, VLC offers an excellent alternative to traditional technology.

However, there exists some challenges that were investigated to make this a viable communication technology. These challenges are dealing with the LOS requirement of VLC, inability to communicate through opaque obstacles, high mobility, ambient light interference, limited LED photon emission rate, required DC biasing, and limited modulation bandwidth as well as the non-linearity nature of LEDs (Dong-Fang Zhang, Y.-J. Z.-Y. (2013)).

As previously discussed, there are several approaches which can be taken to alleviate the main challenges with VLC. To name a few, implementing a MIMO or LED array can be used to increase the SNR and improve diversity in impeding scenarios, channel modelling and equalization at the receiver, camera image sensors used to eliminate ambient light-treated as noise, and finally advanced modulation techniques to overcome limited modulation bandwidth.

FUTURE RESEARCH DIRECTIONS

Since VLC has several challenges as previously mentioned, there has been a fair amount of lab research toward improving its performance as well as improving its distance range. In order to mitigate the channel effect on a VLC system, several techniques have been proposed, such as the usage of Orthogonal Frequency Division Multiplexing (OFDM), and the use of MIMO (Mohammed S. A. Mossaad, S. H. (2015)).

With respect to the limited LED modulation bandwidth, polarization multiplexing methods can be combined with other multiplexing methods which can further increase the communication rate. Cvijetic et al. studied Bit Error Rate (BER)

performance of a polarization multiplexed optical wireless transmission (Chiharu Mukai, K. O. (2012)). Additionally, advanced modulation techniques have been carried out to achieve high data rates up to 100Tbit/s by implementing orbital angular momentum (OAM) with other multiplexing domains and present a free-space data link that uniquely combines OAM-, polarization-, and wavelength-division multiplexing by using three-dimensional multiplexing. (Hao Huang, X. (2014)).

In addition, researchers have looked at combining the Power Line Communication (PLC) technology with VLC, such that the power lines become the data source of these lights (Ding W., Y. F. (2015), Hao M., L. L. (2013)).

CONCLUSION

In this chapter, we have discussed several indoor and outdoor potential applications that VLC can utilize in the upcoming years. Despite its performance challenges, VLC showed significant potential in several indoor and outdoor applications, such as: indoor localization and positions, in-mall advertising and user behavior tracking, and in-plane multimedia broadcasting. For outdoor applications, it shows a promising potential in the automotive industry as well as underwater communications.

KEY TERMS AND DEFINITIONS

CDMA: A channel access method, which allows several users to share a band of frequencies.

Intelligent Transportation Systems (ITS): The potential of adding information and smart communications technologies to the transportation infrastructure and vehicles, in order to enhance transportation safety, mobility, and support productivity.

Light-Emitting Diode: A semiconductor device that emits visible light at a single wavelength when an electric current passes through it. The output from an LED can range from red (at

a wavelength of approximately 700 nanometers) to blue-violet (about 400 nanometers).

OFDM: A method of encoding digital data on multiple carrier frequencies.

Signal to Noise Ratio: A ratio of desired signal to undesired signal (noise) in the average power level of a transmission.

Smart Grid: An electrical grid which includes a variety of operational and energy measures in-

cluding smart meters, smart appliances, renewable energy resources, and energy efficiency resources.

Visible Light Communication (VLC): Data communications medium which uses visible light between 400 and 800 THz (780–375 nm).

Wireless Communication: Transfer of information between two or more points that are not connected by an electrical conductor.

Community Outreach

Loriene Roy

The University of Texas at Austin, USA

Antonia Frydman

The University of Texas at Austin, USA

INTRODUCTION

Community outreach is the extension of library services outside of the physical library. In public libraries, this calls on the library to connect with actual and potential library users. Once primarily associated with serving disadvantaged potential library users, community outreach now refers to any activities libraries develop that deliver services to new constituencies. Community outreach covers the following process: identifying targeted communities, assessing a need, considering responses to this need, prioritizing options, targeting a response to the need, developing the initiative, marketing the response, delivering the program, and conducting continuous and end-of-service evaluation. Of those actions, the process of marketing has received the most attention over recent years. The concept of marketing or ‘selling’ the library and its services has been interpreted as a form of advocacy; not only do libraries inform the public about an individual service, but individual librarians are called on to advocate for their work setting and for the professional at large. The American Library Association (ALA) now considers “Advocacy for Libraries and the Profession” as one of its eight key action areas (American Library Association, 2013). ALA has developed tools for library workers, grouped in a section of its website called “AdvocacyU.”

BACKGROUND

As Heim (now, McCook) pointed out, outreach is much more than opening the doors of an in-

DOI: 10.4018/978-1-5225-2255-3.ch579

stitution; it extends across a spectrum of activities and actions in what Heim referred to as the Stimulation Continuum (Heim, 1984). Outreach involves reaching out to the underserved, and even intervening during times of need.

Early outreach services were designed with education in mind. Early public libraries in the mid to late nineteenth century were founded to further the education of an American public that had little access to other forms of schooling. Libraries, including state library agencies, coordinated broad educational efforts under offices of library extension.

These efforts were followed by programs designed to acclimate new citizens. During that time the Immigrant Publication Society issued small pamphlets to assist librarians in responding to the needs of Jews from Eastern Europe, Russian Jews, and Poles (Carr, 1919). These publications were issued with support from the ALA Committee on Work with the Foreign Born. This committee existed for thirty years, from 1918 to 1948. Over time, these library efforts have been scrutinized more closely and considered by some to be expressions of acculturation.

Heim noted that after 1950, outreach services returned to the educational motif, focusing on adults’ learning needs. And since the 1950s, public libraries provided both general educational services and targeted services for specific clientele. ALA reflected this interest by establishing the Office of Library Service to the Disadvantaged (OLSD) in 1970. In the 1980s, targeted services addressed the needs of latchkey children, business people, and the homeless. The OLSD was renamed the Office of Literacy and Outreach Services (OLOS).

OLOS's mission describes the communities often associated with community outreach:

OLOS focuses attention on services that are inclusive of traditionally underserved populations, including new and non-readers, people geographically isolated, people with disabilities, rural and urban poor people, and people generally discriminated against based on ethnicity, sexual orientation, age, language, and social class. (American Library Association, Office of Literacy and Outreach Services, 2013)

OLOS's involvement with outreach currently includes planning and delivering nationally visible professional events. This includes the annual Dr. Martin Luther King Jr. Sunrise Breakfast Celebration held during each ALA Midwinter meeting, the National Bookmobile day which is celebrated during National Library Week, and events scheduled for the ALA Annual Conference, including the Diversity and Outreach Fair and the Jean Coleman Library Outreach Lecture. In addition, the OLOS website maintains 'toolkits' to assist library workers in their outreach missions. These toolkits include practical advice on serving audiences including the homeless, older adults, and tribal libraries.

For Heim, outreach necessitates creating a climate that supports many activities (Heim, 1982). In 2004, Osborne grouped cases of outreach into six classes: services outside library walls, outreach inside the library, outreach using information technology, technical services, advocacy, and staff development (Osborne, 2004). In her 2010 book entitled *Librarians as Community Partners: An Outreach Handbook*, Smallwood organized 66 examples of library outreach into ten broad categories (Smallwood, 2010). Some categories illustrate that outreach can be designed for specific clientele such as seniors, youth, culturally and ethnically diverse patron groups, and individuals residing in correctional care facilities. Approaches may include classroom outreach, book festivals, or special collections. Outreach can also be grouped

with approaches that share specific techniques such as those that employ local media and those whose success results from collaborations with other agencies, institutions, or companies including arts centers, day cares, restaurants, book stores, and historical societies.

Outreach is not limited to the public library setting or within the library's physical facility. Academic libraries increasingly provide services to their wider community of parents, alumni, and potential library supporters. The services that libraries develop might include instruction, exhibits, lectures, events, and other public programs. Across the globe, outreach services have included various conveyance means to deliver resources and circulating materials, as well as services. Bookmobiles travel to remote areas in the United Kingdom and Scandinavia, while donkeys travel with a cart of books to children in Ethiopia, or use side packs to bring books to children in Columbia (Smallwood, 2010). Alternatively, within library facilities, the redesign of space addresses outreach missions, as patrons have access to learning commons, information commons, and/or social commons.

Outreach has additionally become associated with social justice. One example of this is The People's Library, which was founded by members of the Occupy Wall Street movement (Gray, 2012). Those involved in outreach are recognized for their innovative work, and outreach efforts are often tied to support for intellectual freedom. For example, the Robert B. Downs Award, awarded by the Graduate School of Library and Information Science at the University of Illinois at Urbana-Champaign "acknowledges individuals or groups who have furthered the cause of intellectual freedom, particularly as it impacts libraries and information centers and the dissemination of ideas" (The University of Illinois at Urbana-Champaign, 2013).

Controversies and Problems

Extension of library services beyond traditional roles of collection-building and support for the

reader is controversial to some library workers, and surprising to some members of the library's public. Individual ALA members and even members of the ALA Council (the policy setting body of the association) sometimes express disagreement over whether involvement in social justice issues is supportive of the profession's mission. Those in the profession may question whether outreach aligns with the original missions of education, information, and recreation, and whether extending services is in some way disadvantages the traditional library audience of people seeking a good book to read. This tension is more pronounced during economic downturns, when finances may be limited to improving routine services by developing and implementing new physical and virtual services. Those supportive of outreach reply that literacy programming is an active expression of the service continuum. When library workers develop services to support both existing readers and patrons seeking the skills to become readers, they are affirming not only the library itself, but also the library's commitment to outreach (Heim, 1982).

Libraries have long wrestled with measuring their impact. Starting in the 1930s, national standards were released for public libraries (McCook, 2011). Until the 1960s, these standards were revised each decade, and measured a public library's achievement in numbers of recommended books or hours of service. This approach to evaluation changed in the early 1980s with the publication of the first of a series of planning documents for public librarians. These planning documents provided local libraries with assistance in identifying their roles for a limited period of time, usually five years, and instruction on how to measure whether they had served their community well during that time. Achievement was then measured in ratios called output measures, such as turnover rate or circulation divided by number of volumes held. Public libraries continue to use a suite of planning documents to assess their services.

Academic libraries were typically ranked by the number of volumes held. New measures have

been incorporated over time, including those that measure user perceptions of library services such as the LibQUAL+ project (Snyder, 2002). A number of studies have estimated the economic impact of a library. One such study found that for every one dollar invested in public libraries in the state of Texas, a community receives \$4.42 in benefits (The University of Texas at Austin, 2012). These measurements, however, do not specifically assess the impact of community outreach.

Another less-mentioned challenge regarding community outreach is that it requires special interpersonal skills on the part of the library workers. Librarians involved in community outreach efforts should be aware of the skillsets and competencies required to fulfill a specific service, and attitudes required to serve a specific community. (Montiel Overall, 2009) Being a 'well meaning person' is not the sole predictor of success in working with communities of color (Roy, 2011). In developing outreach services, information professionals must examine their potential role as outsider and the advantages and disadvantages associated with their presence (Roy, 2009). Knowledge about a community, and how to work best within that community is a process that takes time. It involves sensitivity to protocols, good etiquette that guides interpersonal communication within a community.

Solutions and Recommendations

What was once considered outreach is now linked to the concept of community engagement. Responses and solutions to the above challenges are discernable in a myriad of cases of community outreach. Successful community engagement activities include the following key features: belonging, commitment, communication, flexibility, genuineness, relevance, sustainability, and accountability (Sung & Hepworth, 2013).

In the first decades of the 21st century, libraries are responding through *crisis informatics*: assisting those facing disasters or challenges such as job loss. Newer audiences are created out of need. Many libraries reacted to the worldwide

economic recession by developing programs for job seekers (Roy, Brzozowski, Arnold-Garza, & Beauchemin, 2011). In America, libraries contributed to the launch of the Affordable Health Care Act (referred to familiarly in the United States as Obamacare) by offering information sessions and direct assistance to patrons who want to explore, understand, and enroll in healthcare coverage options (Goldberg, 2013).

Contemporary work on community outreach includes studies of communities of need, the preparation of information professionals to serve communities of need, crisis informatics, and work on digital equity.

Selected library services have demonstrated flexibility in the area of community outreach. For instance, reference services were once only patron-initiated and took place through face-to-face contact. With the emergence of new communication technologies, reference services can now be conducted on the telephone, and through an array of virtual deliveries. Whereas a librarian might once have had difficulty finding anything related to a patron's request, now the difficulty lies in narrowing down the search to find the most relevant selections within a vast number of results. Reference library staff have responded to shifting patron needs by incorporating efficiency, instruction, point-of-need services, in addition to more traditional reader advisory services.

Some examples of incorporating outreach into elemental library services are tiered reference, roving reference, and embedded librarianship. Library efficiency is demonstrated through *tiered reference*: a reference model that provides a pyramid of service contacts in which library support staff answer uncomplicated questions and subject specialist librarians answer higher level questions. *Roving reference*—in which reference staff seek out patrons in their facilities to ensure that their questions are answered—is one approach for the internal outreach of reference services. This concept has been expanded in the performance and philosophy of embedded librarianship. *Em-*

bedded librarianship is the extension of the triad of public services—reference, instruction, and reader's advisory—into the community (Carlson & Kneale, 2011).

Serving Communities of Need

As demonstrated by Gratia Countryman, Director of the Minneapolis (Minnesota, USA) Public Library in the early twentieth century, community outreach found a home in libraries (Benidt, 1984). In this case, libraries reached out to community members directly where they lived and worked in locations as varied as factories, hospitals, flophouses, and homeless shelters. State library agencies and national libraries focused on library development, bringing traveling libraries to remote and/or small communities and establishing services for often overlooked community members such as the blind and visually impaired. Recognizing that not all potential library patrons frequented the physical library, public libraries moved outside of their buildings. Over time this was seen in bookmobile services, services in storefronts, and in portable buildings.

Librarians have a lengthy history of serving the reader, and traditional services have been defined by offering print resources and e-resources. Many studies attempt to redefine patron needs by first examining how people seek information in everyday life. Subjects of these studies include people searching for information about adoptions, immigrants living in urban settings, families coping with chronic illness, and survivors of intimate partner violence.

While outreach has had its historical foundation in the public library settings, academic libraries are also reinterpreting their missions through community outreach. Leong summarized outreach activities in academic libraries in three countries: Canada, China, and the United States. He found that outreach was expressed through (1) extending library access to the public; (2) creating information literacy services; (3) entering into

exchanges and other cooperative arrangements; and (4) hosting events such as exhibitions and lecture series (Leong, 2013).

Preparing Information Professionals to Serve Communities of Need

Professional organizations have developed a range of documents that illustrate the skills and competencies expected of information professionals. These include competencies for reference librarians, librarians serving children and youth, and those working in the subject specific areas such as music librarianship and art librarianship. Some national competencies exist, such as the Professional Registration program developed by the Library Association of New Zealand Aotearoa (LIANZA) with the National Library of New Zealand and Te Ropu Whakahau, the national association for Maori in libraries and information management (Library Association of New Zealand Aotearoa, 2013).

Whether explicitly or implicitly, graduates of programs preparing entry-level professionals to work in libraries, archives, and museums are expected to demonstrate competency in the area of community outreach. Three sample competencies are identified, as follows:

1. The Association of Library Service to Children, a division of the American Library Association, issued a competency document that outlines what is expected of public librarians serving patrons ages 0 to 14 years. Such information professionals are expected to provide “library outreach programs which meet community needs and library goals and objectives” (American Library Association. Association of Library Services to Children, 2009).
2. Librarians working in special collections are expected to be “skilled in planning and implementing programs and publications that promote and interpret the collections, such as exhibits, conferences, guest lectures,

public speaking, and other active forms of outreach” (American Library Association. Association of College & Research Libraries, 2008).

3. Standard four of the diversity standards for academic librarians asks that “Librarians and library staff shall develop collections and provide programs and services that are inclusive of the needs of all persons in the community the library serves” (American Library Association. Association of College & Research Libraries, 2012).

Specific academic programs have provided opportunities within their curricula for students to participate in community outreach, oftentimes through service learning activities. These can be operated as individual initiatives such as “If I Can Read, I Can Do Anything,” a national reading club for American Indian children and youth that is managed by students and their advising faculty member in the School of Information at the University of Texas at Austin. Students in the School of Library and Information Studies at the University of Alabama (USA) provided computer training with community members with disabilities living in west Alabama. Students can focus on specific civic engagement through independent studies, internships, Capstone or graduation projects, or through opportunities embedded within a formal course.

Several graduate programs accredited by the American Library Association have provided special opportunities for students to work directly with communities of need and/or to prepare librarians in these communities. The School of Library and Information Studies in the University of Alabama USA’s College of Communication and Information Studies offered Project ALFA, Accessible Libraries For All. AFLA focused on gathering data and helping students acquire skills in serving library patrons with disabilities. Simmons College in Boston, USA, collaborated with Harvard by means of a grant from the National Endowment for the Humanities to assist staff at

Iraqi libraries. The School of Information and Library Science at the University of North Carolina USA hosted ELIME-21, Educating Librarians in the Middle East: Building Bridges for the 21st Century. Students at the University of North Texas's Department of Library and Information Sciences collaborated to help address the needs of those living in rural areas in Jamaica. The Graduate School of Library and Information Science recognized the needs of communities and students by forming the Community Informatics Research Laboratory.

Crisis Informatics

Emergency responses may replace traditional library services, especially when a natural disaster strikes. Faculty at the University of Toronto (Canada), Florida State University (USA), the University of South Carolina, and University of Washington (USA) have studied what information is needed during the early warning phases of emergencies, technology used during the 2010 Chilean earthquake, use of information in reducing HIV/AIDS in Uganda, and preparing for and responding to hurricanes.

Digital Equity

Efforts toward reducing the digital disparity involve bringing technology and training to audiences that might not otherwise have access to equipment and learning opportunities. The Bill & Melinda Gates Foundation has demonstrated how issues of technological equity can be addressed nationally through its American libraries initiatives. Over a period of five years, the Foundation brought hardware, software, and training to public libraries in all fifty U. S. states, starting in the states with the highest percentage of children qualifying and receiving free lunches in the public schools. Before this initiative launched, only about one in four of American public libraries offered free public access computing. At the end of the program,

99 percent of the libraries provided these services (Gordon, Gordon, & Moore, 2001).

The Foundation extended the U.S. library program to tribal communities in the states of Utah, Colorado, New Mexico, and Arizona, with the Native American Access to Technology Program. After this program wrapped up, the Foundation supported the development and services of a web portal called WebJunction. WebJunction has built an online community that offers distance delivery of continuing education to library workers, as well as targeted services, including technology training in rural libraries, and among Spanish speaking clientele and job seekers (Mason, 2009). At the international level, the Gates Foundation has annually recognized innovation in providing free public access to the Internet through the Access to Learning Award. Past recipients have provided Internet access at rural markets in Guatemala, to children and their families in rural schools in China, to urban centers in Columbia, and to farmers in Africa. Recipients are recognized at the International Federation of Library Associations and Institutions (IFLA)'s World Library and Information Congress along with an award of \$1 million USD.

FUTURE RESEARCH DIRECTIONS

Those teaching and conducting research in schools of information might be involved in a wide range of investigations that address community outreach. Today, these areas include community informatics, medical informatics, global information justice, service learning, action research, evidence placed practice, information seeking, and information coping.

While an individual or organization can make a great impact on addressing community needs, the wants are unending and vast. Connectivity is still a challenge. Broadband access is practically inconceivable in many areas around the world. In Alaska, USA, for example, telephone confer-

ence calls are still more reliable than web based teleconferencing. In rural Native Alaskan villages, Internet access may be limited to one user and one computer at a time (American Library Association, 2011). Along with connectivity, a major challenge to digital equity is sustainability. Even with the help of major funders, initiatives usually have limited financial support. At the same time, there is a constant demand for retooling the skills of information workers, refreshing equipment, and meeting the needs of wave after wave of new library patrons.

There is a call for libraries and information settings to continually document their impact. Those working in and supporting information settings are encouraged to look beyond input measures such as resources added or outputs such as circulation of materials and attendance, in order to consider new ways to measure not only cost effectiveness but return on investment. In 2007, the Urban Libraries Council identified outreach to caregivers and parents as a key strategy for supporting early literacy. Outreach initiatives such as this one would create a network of partnerships committed to helping prepare the youngest citizens for school readiness through early literacy support (Urban, 2007).

CONCLUSION

Community outreach has existed as an essential reflection of the vision and mission of libraries since the beginnings of the public library movement. The elements of outreach have involved serving all members of the library's geographic boundary and beyond. These expressions have included supporting and advancing literacy as well as assisting patrons in meeting the needs, challenges, opportunities, and tragedies of their everyday lives. Such services are challenged by budgetary constraints, problematic motivations among some service providers and patrons, and varying access to technology. Still, community outreach is the local, national, and international

stage that showcases what libraries can do best: providing an equitable playing field for access to the world of knowledge.

KEY TERMS AND DEFINITIONS

Advocacy: Informing the public of the library offerings, the library as work setting, and the library profession.

Community Informatics: Designing services for targeted members of the library's user community.

Crisis Informatics: Designing services that assist library patrons who are impacted by, or might be impacted by, traumatic events.

Digital Equity: Promoting and designing services that provide all members of the community with access to online information and the skills and tools to access, use, and evaluate online content.

Information Coping: The ability to handle news, alerts, messages, data, music or other information formats in a way that results in learning and understanding with minimal anxiety.

Information Seeking: The habits and patterns that humans undertake in locating answers to questions, satisfying needs, and fulfilling desires for learning and entertainment.

Service Learning: Addressing community needs through course content and personal reflection.

Exploring “Hacking,” Digital Public Art, and Implication for Contemporary Governance

P**Amadu Wurie Khan***University of Edinburgh, UK***Chris Speed***University of Edinburgh, UK*

INTRODUCTION

This article presents the application of the online (Internet) ‘hacking’ concept to community life and processes from two hypothetical contexts: First, it was hypothesised that technology could be ‘hacked’ into by disadvantaged communities to create a digital public art. Second, the community-generated digital art platform could in turn be used to ‘hack’ into images and memories to facilitate the sharing of conversations and identity, social engagement, and digital inclusion among residents. The article therefore presents how these contexts of the characteristics and practicality of online ‘hacking’ inspired the design and functionality of a community digital artwork in a disadvantage urban estate in Edinburgh, UK. In addition, the article considers the implication of the ‘hacking’ practices by and among disadvantaged communities for realizing the social action, social engagement and networked society goals of the UK Government’s ‘Big Society’ policy. This is significant because the ‘Big Society’ agenda promotes an interactive networked culture that has transformative potential to connect citizens, build knowledge and continuous learning and regenerate communities at a time of economic austerity in the UK (Mayo & Steinberg, 2007; Speed, Khan & Phillips 2016).

The article is presented as follows. The following section is the conceptual path-clearing.

It traces the etymology and usage of the concept of ‘hacking’ from the techno-scientific domain. Section three makes an attempt at disambiguating the kinds of ‘hacking’ practices that are relevant to issues of community relations and processes. Section four presents the practical application of the ‘hacking’ concept that culminated in the social design of a physical digital public art, the ‘totem pole’. In section five, the implications of ‘hacking’ for the ‘Big Society’ policy is considered. Section five provides suggestions for a research agenda that could generate future design interventions that are inspired by concepts associated with digital media culture and for realizing forms of contemporary governance such as the ‘Big society’.

CONCEPTUAL BACKGROUND: THE “HACKING” FOLKLORE

In tracing the etymology of ‘hacking’, folklore rather than the history of the concept should be prioritised. This is because there are many narratives to explain the emergence of the concept and its incorporation into contemporary public discourse (Devitt, 2001). History could be subjective, but mainly expected to be a precise and accurate record. Folklore, although rooted in historical narrative and passed down across generations, is not expected to carry the kind of accuracy as history should. This is because its mainly verbal

form of transmission and its inherent performance element makes folklore vulnerable to variability and manipulation (Khan, 2009). A word of caution though! History could be handed down verbally too, and like folklore could be accurate, written down and passed through generations. Nonetheless, folklore is associated with traditional stories, gossip, myths and legends, all of which are traditional art forms that are characterised by dubiety, as might be the case with history. A look at the many romanticised accounts of the origin of ‘hacking’, lends weight to prioritising the folklore around the origin of the concept over historical accounts.

Against this background, folklore has it that ‘hacking’ originated from the realm of technology as student slang at the Massachusetts Institute of Technology (MIT) between 1950 and 1960 (see Levy, 2002; Devitt, 2001). MIT is said to have been amongst the first institution to offer courses in computer programming and computer science, and that it was on such a course that group students taking a class on artificial intelligence came to coining the word ‘hacker’. Students used the term to refer to their ability to manipulate a computer to perform actions not intended for that program. It has also been suggested that the term was used to convey a sense of performing a “practical joke and feeling of excitement because the team member would ‘hack away’ at the keyboard hours at a time.” (Moore, 2006). Examples of ‘hacking’ folklore associated with MIT include: in 1964, MIT students (hacks) placing a convincing replica of a campus police car on top of the Institute’s Great Dome as a form of practical joke, manipulating electric trains to make it perform faster and more efficiently (see Levy, 2002; Moore, 2006). Ward (BBC 27 Oct 2000), argued that ‘hacking’ originally meant “an elegant, witty or inspired way of doing almost anything”. Since then, the practice of ‘hacking’ has been evident in or applied to other fields and scholarly or technical communities, and not just limited to technology. The next section briefly explores these folkloric dimensions of

‘hacking’, namely ‘phreaking’ & ‘cracking’, and ‘hobby-ism’ & ‘prosumerism’.

“Phreaking” and “Cracking”

In the 1970s, ‘phreaking’ or phone ‘hacking’ emerged by which ‘hacks’ manipulated telephones to make free calls. A legendary figure in this respect was, a ‘phreaker’ John Draper, who discovered that a whistle included as a free gift in boxes of Captain Crunch cereal emitted a 2,600 hertz pitch which was the frequency used to indicate operator calls to phone exchanges (Burnham, 2009; Lapsley, 2011). Blowing the whistle into the mouthpiece of the phone meant that the call was seen to come from an operator and hence no charges were levied on the call. Not only did John Draper become known in the hacking world as Captain Crunch, but his work is seen to have inspired Steve Wozniak and Steve Jobs who went on to found Apple Computers (Burnham, 2009). By the 1980s, ‘phreaking’ was evident in computers in the form of Bulletin Board Systems (BBS), which is believed to be the precursor to the yahoo groups of today (Levy, 2002; Lapsley, 2011). In addition to enabling individuals to post messages of any kind of topics, the BBS specialized in disseminating information on how to break into computers, how to use stolen credit card numbers and share stolen computer passwords (see Levy, 2002). Known as ‘cracking’, the practice entails the circumventing computer security and unauthorized remote computer break-ins via a communication networks such as the Internet.

From the above practices, two distinct but interconnected senses of the term ‘hacker’ and ‘hacking’ in the domain of technological science are discernible: the modification of use and the breaking of codes/security (Raymond, 2001). This often came together in particular ways to establish particular but interconnected areas in the domain of technological science: computer programming and computer security. In the former sense of the term ‘hacker’, emphasis is put on modifying computer programmes/technologies

so that they can perform new uses, while in the latter (code-breaking) the emphasis is placed on breaking security features, either as an end in itself or as a way so that the technology can be used in ways other than originally intended. It has been suggested that the terms ‘hacker’/‘hacking’ might be restricted to the first sense, whilst the terms ‘cracker’/‘cracking’ might be used to refer to the second set of practices (Cramer, 2003). According to Raymond (2001), ‘hackers’ from the field of programming usually work openly and use their real name, while computer security hackers (or crackers) prefer secretive groups and identity-concealing aliases. Also, their activities in practice are largely distinct. The former focus on creating new and improving existing infrastructure (especially the software environment they work with), while the latter primarily and strongly emphasize the general act of circumvention of security measures, with the effective use of the knowledge (which can be to report and help fixing the security bugs, or exploitation for criminal purpose) being only rather secondary.

“Hobby-ism” and “Prosumerism”

There is another sense in which ‘hacking’ and ‘hackers’ include ‘hobby-ism’, in which case individuals show commitment and passion in being creative in a given field in ways that are similar to professionals (Burnham, 2009). An example often cited is that of ‘circuit bending’, a practice associated with the techno-music sub-culture. By this way, ‘hobbyists’ customized the circuits within electronic devices such as low voltage, battery-powered guitar effects and small digital synthesizers to create new musical sound (Burnham, 2009; Early, 2007; Levy, 2002). This results in the creation of the strange, dis-harmonic digital tones that became part of the techno-music style. ‘Hobbyists’ are in the main customers of products who rather than just accept the manufacturer’s design of a product, will try to adapt it to their tastes in order to get a desired aesthetic and utility

value. It has been observed that such activities have been tapped into by manufacturers in an attempt to widened customer base and profit margins. This is by the appropriation of ‘hacker’/‘hobbyist’ generated designs or specifications into new products that are sold into the market. The ‘hacker’ or ‘hobbyist’ therefore transforms from a consumer to what Toffler (1980) referred to a ‘prosumer’. In this situation (prosumerism), the role of producer/professional and consumer merges to participate in the design and production requirements of products through mass customisation. Manufacturers adapt or create their products to the specific requirements of consumers in order to keep the latter satisfied, while generating profit.

Others argued that ‘prosumers’ include consumers who rather than just accept or purchase what is on sale would actively search the market and seeks to influence the market (Crakburn, 2003). ‘Prosumers’ therefore do not only influence or dictate design, aesthetic and utility values, but also influence the markets. In this sense, ‘prosumerism’ arguably makes consumers part of the creative and marketing or pricing process, as they impart their individual and or collective preferences.

The above folkloric account illustrates the nebulous origins of ‘hacking’ and its manifestations (phreaking, cracking, hobby-ism, and prosumerism) within science and technology: mechanics, computers (both programming and security), and telephonics, as well as in manufacturing. These manifestations of ‘hacking’ continue to be shrouded by accounts that have been subjected to manipulation and variability, and therefore continues to be the terrain of folklore. This, in turn, makes ‘hacking’ a romanticized construct, and a contested concept (Devitt, 2002; Thomas, 2002). ‘Hacking’ has therefore become a metaphor for the practices and actions that exploit (or explore) weaknesses or deficiencies in a system to behave or function in a certain way (Kulikauskas, 2004). The next section takes a look at some key social characteristics of ‘hacking’.

“HACKING”: AND ITS SOCIAL CONTEXT

Arguably, the actions by ‘phreakers’, ‘crackers’, ‘hobbyists’ and ‘prosumers’ constitute a creative process that is performed in a social environment (see Kulikauskas, 2004). The socially creative process involves risk-taking or the circumvention of limitations, and entails self-reliance, and learning through the sharing of skills and resources (Fitch, 2003). The creativity is motivated by intellectual, functional and aesthetic challenges (see Cramer, 2003). It is also a conscious technical act or practice that individuals undertake towards a preconceived outcome that was not intended by the original creators of the ‘thing’ that is ‘hacked’ (Levy, 2002; Dan, 2011). It therefore has the following social characteristics, namely reciprocity, resilience and moral ambiguity (Fitch, 2003; Lemos, 2002).

“Reciprocity” and “Resilience”

‘Hacking’ depends on reciprocity. This is better exemplified in computer gaming. As Crabtree (2003) explains, when people are stuck in a computer game, they will go to a gaming community online, and ask others for advice. Other gamers will help on the principle of reciprocity; they will sometime in future expect someone else (including those they have helped) to help them out with their gaming problems. Reciprocity is therefore a form of harnessing social capital among society’s members. Through reciprocity people turn to each other when they encounter everyday problems (civic, social, political, economic etc.) to access knowledge, skills, and advice from others who have expressed similar problems in a bid to solve or help overcome them. ‘Hacking’, in this sense, becomes a social, or in Crabtree’s conception a ‘civic’, phenomenon (Crabtree, 2003). It thrives on symmetrical and synchronous relationship. as well as on individual and collective resilience to cope with emerging problems and demands that citizens (non-citizens too) encounter in their everyday lives in the community (see Crabtree, 2003).

This is not to say that ‘hacking’ is always motivated by reciprocity. It might be that there are altruistic and communitarian reasons behind an individual’s sharing of skills and resources to facilitate ‘hacking’. For example, helping others may be a source of ‘feel-good’ factor as well as perceived as a civic and social responsibility that an individual owes to others. It might also be that some individuals might not give back or reciprocate either in the same way or in kind as other participants. They simply just take away, consume or benefit from what others have contributed without returning such favours; neither would they expect similar favours from others who benefit from their contribution. In this case, the relationship is asymmetrical and asynchronous by which an individual may not reciprocate magnitude and content or information as required. It is also possible that in cases of reciprocal response, this is not spontaneous, but deferred to a later date (Hrastinki, 2008).

The “Moral Ambiguity”

From the foregoing discussion, it could be suggested that hackers’ socially creative practices could be perceived to be ‘legal’ or ‘illegal’ (Fitch, 2003, Lemos, 2002). For want of clarity, we suggest that, the term ‘hacking’ is reserved or applied to ‘legal’ activities, while ‘cracking’ is for the ‘illegal’ or transgressive ones as Figure 1 shows.

Yet, we know that these conceptualisations are fraught with ‘moral ambiguity’. By ‘moral ambiguity’ is meant that individuals’ perceptions and interpretations of the legitimacy of a ‘hacking’ practice is subjective and influenced by their moral values and beliefs. This begs a three-dimensions to conceptualizing ‘hacking’ as Figure 1 shows. At the extreme left and moving towards the right of the continuum [up to point zero (0)] of Figure 1, are forms of positive ‘hacking’ that are normally perceived as good and legitimate or legal. Examples of this kind of ‘legal’ activity encompasses ‘hobbyists’ and ‘prosumers’ as indicated in Figure 1. As ‘hobbyists’, they are not necessarily profes-

Figure 1. The “hacking”/“cracking” continuum

sionals, but amateur enthusiasts seeking to adapt and influence the aesthetic and utility value of a product. ‘Hackers’ are ‘prosumers’ because they openly and ‘legally’ participate in the designing and production chain from the outset as well as influencing market forces. The activities are, in the main, facilitated and supported by manufacturers.

‘Cracking’ is diametrically opposite to this practice, widely perceived as illegitimate or illegal and indicated on the extreme right of the continuum [moving from point zero (0) to the right]. Examples normally perceived as illegitimate and transgressive actions include code-breaking, ‘phreaking’ and phone tapping. However, ‘code-breaking’ can be perceived as ‘legal’ and or ‘transgressive’ depending on an individual’s moral standpoint. There is therefore the possibility of a continuum of ‘hacking’ and ‘cracking’ practices, which could be designated as ‘morally ambiguous’, which is around ‘point zero’ (0) or in the middle of the continuum. It should be envisaged that there will exist a plethora of on-line and off-line practices that could be located in the continuum, albeit it underpinned by the moral persuasion of individuals. More importantly, what constitute ‘legal’ or ‘illegal’ and their boundaries of demarcation are not only based on an individual’s ‘subjectivities’, but also constructed by legislation and policies of states, supra-national institutions and industry. Nonetheless, the illustration is intended to serve a heuristic purpose that is informed by the perception of individuals in ascribing ‘good’/‘bad’ or ‘legal’/‘illegal’ to ‘hacking’. The illustration also demonstrates that both ‘hacking’ and ‘cracking’ practices are underpinned by imaginativeness, intentionality and functionality (see Lemos, 2002; Fitch, 2003).

The above characteristics and application of ‘hacking’ provided the inspiration for a community-generated digital art, known as the digital ‘totem pole’ (see Chris et al. 2016). The key hypothesis was that technology could be ‘hacked’ into to create a digital public art, which have implications for the realization of UK’s ‘Big Society’ policy among disadvantage communities. The rest of the article presents how online ‘hacking’ inspired the social design of the ‘totem pole’ and its utility for community life and processes.

FROM THEORY TO DESIGN APPLICATION

This section is divided into two parts. The first describes the design locale and process of community engagement that culminated in the construction of the public digital artwork. This is followed by a discussion of the practicality and functionality of the digital ‘totem pole’ for the ‘Big Society’ as a form of contemporary governance.

Wester Hailes and the Design Process

Wester Hailes is a huge housing estate constructed in the 1970s on the Western outskirts of Edinburgh, the capital city of Scotland, UK. It has been afflicted with high levels of social and economic deprivation, crime and unemployment. The social and economic challenges of the area have provided the impulse for local residents to organise community development and service delivery initiatives. In addition, Wester Hailes has historically deployed community art towards

achieving community development, regeneration and empowerment. Community art has also been central to the desire to project a positive image of the community to contrast a mainly negative representation of its residents.

Two local service providers, Prospect Housing Association (aka Prospect) and Whale Arts expressed an interest in using social media as a platform to share ideas, photos and memories. Prospect set up a Facebook page and began posting images of the area that were originally published in the community newspaper; the *Wester Hailes Sentinel*; latterly the *West Edinburgh Times*. The page quickly became popular and with photographs attracting many comments about who, when and where they were taken (<http://on.fb.me/mOPPwp>). This ‘write back’ facility began to enable residents to recover memories of the past and drew out many connections beyond the image itself. By the summer of 2010, the research team and local residents agreed on a design method that encapsulated ‘hacking’. This involved the development of platforms that facilitated the public ‘writing back’ on to the photos and images of Wester Hailes. To enable this process, community members chose the construction of

a large wooden digital ‘totem pole’ to be located within the neighbourhood.

WHALE Arts coordinated the production of the ‘totem pole’ (see Chris, Khan & Phillips, 2016). A steering group of community members and project partners was created to ensure that clear targets are set and achieved. The steering group also facilitated networking, engagement and capacity building that underpins the five participatory workshops within the community (Figure 2).

The workshops were held during local civic events including the Tenth anniversary celebration of the Union Canal, at the AGM of service providers including the Prospects Housing Association and WHALE community arts project, and at the annual community Road Show in the Westside Plaza shopping centre. Participants to the workshops include local residents, staff of services and community activists. Project staff used the workshops to explain the rationale, process and outcomes with a view to generate interest and recruit local residents to participate in its development and delivery.

A central element of the workshop was the display of a portable banner with embedded quick

Figure 2. Residents learning to scan

response (QR) codes (as proof of concept) and historical photographs depicting people, events and places of Wester Hailes on the outer wall of a portable shed (see Chris, Khan, & Phillips, 2016). Both the portable banner and photographs were used in combination to introduce local residents with different levels of technological expertise and interest to the technology used in the project. Participants were asked to look at the photographs to trigger their memories or any other associations that they might have with the

people, event or place depicted. They were then encouraged to share their story/memories about these, which were captured through a voice and film recorder. Participants were also encouraged to scan the QR codes embedded on the photographs and to record their stories and upload them to the *Tales of Things* website (and the Wester Hailes social history archive). They were then asked to scan and listen to the replay. This exercise was to give them experience of the opportunities that the technology would offer, which is the ability to read and write into the codes. The workshops were also opportunities for participants to ask questions and provide any suggestions or views about the project and how best to improve it and to get their sustained involvement in its future development (see Chris, Khan & Phillips, 2016). The overall ethos of the workshops was one that promoted engagement with local residents and their exposure to new developments in web-based technology in a way that was empowering, collaborative, non-threatening and meaningful. The workshops were therefore central to community participation in all aspects of the totem pole project including the design, time-scales and location of the 'totem pole' (see Chris, Khan, & Phillips, 2016).

During the carving of the pole and the ensuing deliberations, both residents and service providers realised that the pole had a potential for service delivery in the locality. It was therefore decided that, in addition to sharing stories and memories of the area, the 'totem pole' should include 5 QR codes that give access to a variety of services. The final product was a carved wooden digital 'totem pole', which was situated within Wester Hailes (Figure 3 above). Its QR codes provided a physical platform for 'hacking' images (through the ability of people being able to comment and create new meanings for the images) and sharing conversations about the area. The QR barcodes were also gateways to cloud based material relevant to the location of the pole. Local residents could scan one of the labelled tags to access and contribute to historical photographs, stories, video and audio clips (Figures 4 and 5). By so doing, the pole act

Figure 3. The installed digital "totem pole"

Figure 4. Local residents scanning the QR codes

Figure 5. Use of historical photos to evoke memories of past community activists. Residents could “write” memories on to QR codes and attach them to the photograph.

as a social resource to help build connections between the people and the place, as well as drawing upon online resources (see Marggets, 2011; Chris, Khan & Phillips, 2016).

What then can be concluded from the design and practicality of the ‘totem pole’ that is relevant to developing an understanding of the intersection of the digital media culture of ‘hacking’, public art, and the ‘Big Society’ policy? To answer this question, a brief account of the main features and aims of the policy would be imperative.

“Hacking” and Implications for the “Big Society”

The ‘Big Society’ is a policy mainly championed by the governing Conservative Party in the UK (Szieter & Ishkanian, 2012). It is aimed at encouraging citizens (and non-citizens) to participate collectively and collaboratively in local initiatives. It is intended to make policy-makers transparent and accountable to the recipients of public services. By so doing, the policy is a bottom-up

process that transforms policy-making and service delivery from a centralised bureaucratic control system to one that is grass roots-led. It's proponents argued that this would make service provision decentralised and localised. Proponents also argued that this 'localism' enable services to be tailor-made to the needs, tastes and specifications of local people, and at the same time delivered in a better improved quality (see Lesley2010). In this sense, service users (citizens) are constructed as not only consumers, but 'prosumers' as they become stakeholders in the design of services from the outset of their conception and formulation. As 'prosumers', citizens depend on each other to pull skills and resources together for mutual benefit. Grass-roots involvement in the formulation, delivery and making choices on services, access information and knowledge, and hold public officials to account make them become empowered social actors (see Chadwick, 2009). The 'Big Society's' originator, British Prime Minister David Cameron claimed that the policy will enable people powerful enough to help themselves and is the "biggest, most dramatic redistribution of power from elites to the man in the street" (Green Paper No. 14). The policy could enable a fluid and evolving response by individuals to challenging circumstances, eradicate structural inequalities, and facilitate civic engagement, social connectivity, networking, and innovation (see Szieter & Ishkanian, 2012).

Given these goals of the policy, the 'totem pole' became relevant to the 'Big Society' agenda among the research team, and residents. It serves as a networked museum or repository for audio, written and visual recordings of current and past memories, images, narratives, works and ideas of local residents and others in the Diaspora. While these benefits of community digital art have been observed elsewhere (see for instance, the 'Talking Poles' in Moulder et al., 2011), the totem pole moved beyond its aesthetic and archival value to have a symbolic relevance to Wester Hailes as a community with historic problems of marginalisation. The general feeling among

residents was that the 'totem pole' served a symbolic function – that of community resilience and regeneration. It symbolises the community's resilience to contest negative depictions of their community as afflicted with social delinquencies and deprivation. The process of designing and delivering the totem pole depended on the input of residents. As others have observed, most public artwork that incorporate digital technology and produced by non-professional artists tended to exclude people from the final stages of the creative process (Moulder et al., 2011, p.2). In contrast, the pole's social design approach facilitated community participation at every stage - from the design process of the pole and the QR codes, the content and themes therein contained to the installation of the finished product. The pole's design therefore reflected residents' design preferences, aspirations and expectations of their locality (see Chris, Khan & Phillips, 2016). It made residents to be co-creators of the artwork and for them to have equal ownership of the whole project.

The design process also contributed to the skills of locals for it to be a successful participatory community art project (Moulder et al., 2011, p.8; Ackoff, 1974). The lack of digital technology skills including social media, therefore, did not preclude anyone from participating. As explained earlier, the workshops built such skills among those that lacked them. Overall, the process of design nurtured an engagement between professional and non-professional artists, academics and non-academics, and digital media technologists and non-technologists. The social connectedness and networked communities was only possible by the in-built 'read-write' component of the 'totem pole'. In this way, the project generated significant social capital by engaging with the diverse ages, backgrounds and interests present in the Wester Hailes community to explore and capture their memories of the area. It is also to articulate a collective future ambition for the community.

In summary therefore, as a 'hacking' inspired design intervention, the collaborative production of the 'totem pole' became tangible to the ideals

of the ‘Big Society’ agenda. Firstly, it was an embodiment of social action, civic engagement, and networking. This is because it was co-produced artwork between residents, service providers and the academic/research team to realise the community’s aspirations. Secondly, it generated a sense of community, empowerment, and identity with the estate among residents (Tonnies, 1957). This sense of community moved across geographies of locality, Diaspora, shared interest and generations. By so doing, it generates a feeling of identity with Wester Hailes among these disparate geographies. Thirdly, the sharing of images and resources constitute resilience, resourcefulness and reciprocity. For instance, the renewed sense of identity, participation in the design and use of the pole demonstrates the resilience of residents to regenerate their community at a time of decline in services such as local newspapers and economic austerity. The sharing of information, memories and images largely depend on the community pulling together its resources in a way that is reciprocal (see Chris, Khan & Phillips, 2016). These positive social processes are akin to ‘civic/social hacking’.

However, it was the view of some residents, service providers and the research team that the ‘pole’ might be used by the public in deviant or transgressive ways. For instance, there were concerns that its ‘read-write’ facility might attract unfair, impolite and gratuitous comments against residents, service providers or politicians. If these were to occur, they would constitute ‘cracking’, a phenomenon associated with the ‘hacking’ culture as enunciated earlier. To address this unwanted and transgressive use of this public art technology, an editorial policy was put in place to moderate and monitor public comments before being posted on to the ‘pole’. Although this was done in consultation with residents, it presents a moral and ethical dilemma that would confront any digital project that is community-led as would be with the ‘Big Society’ policy. For instance, how would the powers that be (meaning researchers,

services, policy-makers and politicians) respond to activities of communities that are outside the stipulations or rules of engagement of a public art or service? Would the transgressive behaviour by individuals and communities, albeit it in their own interest and benefit, be tolerated? If tolerated, then it would make citizens to act like ‘prosumers’ who are involved in deciding on the type of service and how it is used or its usage. The extent to which such individual and collective interventions are acceptable or not acceptable, justified or not justified and whether or not they constitute social deviant behaviour are bound to be debatable.

In addition, the participation and reciprocal relationship among stakeholders (meaning researchers, services and residents) in the production and functionality or workings of the pole could be asynchronous, rather than synchronous. For example, in a socially disenfranchised community like Wester Hailes, not every one had access to the Internet or interactive mobile phones (see Chris, Khan & Phillips, 2016). Many individuals could not afford the financial resources and skills required to use this technology, despite the training provided as explained earlier. These individuals are not likely to benefit from this ‘hacking’ activities that the functionality of the ‘pole’ depended on. This could further widened the gap between the empowered and the marginalized as level of participation based on their abilities and resources at their disposal are uneven. It is a potential risk to achieving the ‘Big Society’ agenda: not all individuals and communities will participate either in all services or activities or in equal measure. The project claimed to promote digital inclusion in so far as many residents who had no experienced of interactive media were provided with the skills to use the ‘pole’. Nonetheless, the structural inequalities in society are bound to affect, in different ways, individual and community participation in the technology.

Another moral dilemma was that, Internet-facilitated ‘hacking’ has an uneasy relationship with the goals of the ‘Big Society’. Firstly, this

type of 'hacking' is mainly virtual (internet), and confronts the purpose of face-to-face social contact, social interaction and social engagement among citizens. Secondly, the 'hacking' through everyday social practices and sharing is conducted on a voluntary basis, albeit with the expectation of reciprocity. In the context of the 'Big Society', it is likely that such commitment and voluntarism will vary among society's members. The received wisdom is that volunteering is the terrain of the middle class, and so deploying 'hacking' as a mechanism for pursuing the 'Big Society' agenda might exclude disenfranchised communities (see Chris, Khan & Phillips, 2016).

FUTURE RESEARCH DIRECTIONS

The exploration of the 'hacking' concept and its application in social design and policy interventions is heuristic. Research and design energies should therefore be devoted towards understanding the intersections between online practices (virtual communities) and offline practices, or the daily experiences of individuals in the policy context of contemporary governance. The nature of the investigation should aim at offering radical insights into how disadvantaged communities will develop any means possible to overcome the challenges they face especially at a time of financial cuts that are likely to impact upon them. These design and research interventions could be understood through the use of cross-disciplinary research: social science, arts and humanities and industrial models of co-design with communities that are impacted by policies.

In addition, it has been highlighted that 'hacking' is a practice that is fraught with moral ambiguity: that of whether it is acceptable or non-acceptable to practice 'hacking' (Kulikaskas, 2004). The pejorative conception of the term is compounded by contemporary media representation of 'hacking' as criminal and social delinquency. 'Hacking' in this sense is associated with criminal acts such as identity theft, credit card

fraud and other computer-related crimes (see also Moore, 2006). The 'phone hacking' saga in the UK culminating in the judicial 'Leveson Inquiry' in 2011/2012 is a reminder that, in addition to legislative and policy considerations of the state and industry, moral ambiguity play a role in the public determination of what constitute legitimate or illegitimate 'hacking' (Leveson, 2012). The criminal connotation of the term is believed to have caused a segment of the computer community to ascribe the term 'hacker' to those engaging in legal activities. As already explained, they ascribe 'cracker' to those engaging in nefarious 'hacking' activities including those performing computer break-ins. Nonetheless, the term continues to be used by actors in the techno-scientific field for two reasons: firstly, the intended meaning can be based on the context of usage in order to clarify which meaning is intended (pejorative or complimentary); secondly, the practice describes a set of skills which are used for various reasons including nefarious criminal activity (Moore, 2006). Researchers should therefore engage in empirical investigation to gather evidence to inform this debate about what is morally legal or illegal, and who has the right or moral authority to decide these activities as indiscretions.

Research should also investigate (empirically and or conceptually) the utility in employing the terms 'social or civic hacking' and 'social or civic cracking' for depicting forms of 'hacking'. Questions that could be empirically explored include: Should the term 'social/civic cracking' be applied to hacking activity among communities that are 'illegal', transgressive or contravenes social norms, policy and legislation? Conversely, should the perceived community 'legal' hacking practices be ascribed as 'social/civic hacking'? Exploring these areas would develop our understanding on how communities use digital technology for empowerment, resilience and resourcefulness beyond that which the state is currently willing or able to provide.

Finally, all of the aforementioned research areas could also focus on affluent or middle class com-

munities. This would enable an understanding of the motivations, aspirations and resourcefulness of this segment of society in harnessing technology for transgressive or legal pursuits to cope with the challenges they face. Such research should generate insights that would enable a comparative understanding of the use of technology along socio-economic demographics in the polity. It will also counterbalance stereotypes of 'hacking' as a practice undertaken by a certain section of society.

CONCLUSION

This article has explored how the concept of 'hacking' provided the inspiration for a community-based digital artwork that facilitated social engagement, connections, and shared identity in a disadvantaged neighbourhood in an urban setting. This example highlights that digital media culture have utility for addressing everyday life situations, and the capacity of individuals and communities to develop or organize innovative social solutions, whether transgressive or conformist to established protocols (norms, laws) for the improvement of their lives and neighbourhoods.

The chapter also considered the moral dimension to evaluating 'hacking' and the distinction between 'hacking' and 'cracking'. Nonetheless, it has been explored that, whether or not social processes are 'hacking' or 'cracking', they have the characteristics of a community (virtual or actual). This is because they are a manifestation of empowerment, resilience and resourcefulness by individuals to access or generate benefit beyond that which the state is currently willing or able to provide. The chapter also provides suggestions for a research agenda that could generate future design interventions to develop an understanding of how digital media culture could inform forms of contemporary governance such as the 'Big society'.

KEY TERMS AND DEFINITIONS

Folklore: Generally refers to forms of cultural expressions, which people use to convey and share their history and identity. It incorporates narratives, jokes, beliefs, proverbs, legends, myths, music, songs, dances, costumes, food, and festivals.

Hacking: Describes the practices and actions by which individuals and communities’ exploit (or explore) weaknesses of a system and product, which could be technological or social, to get by. It encapsulates both transgressive or ‘illegal’ and resourceful or ‘legal’ practices that individuals undertake to circumvent or respond to technological and social challenge or circumstance.

Hobby-ism: This refers to a form of ‘hacking’ process and practice by which an individual customize or adapt a product to one’s preferences or tastes to get a desired utility value. People who indulge in this practice are called ‘hobbyists’, and by extension are those customers of products who rather than just accept the manufacturer’s design of a product, will try to adapt it to their specification.

Prosumerism: This is a form of ‘hacking’ process by which the role of producer or professional or manufacturer and consumer merges to participate in the design and production requirements of products through mass customisation. The end product is a situation where manufacturers adapt or create their products to the specific requirements of consumers to satisfy the customers and generate profit.

QR Code: An abbreviation of Quick Response Code. It is a barcode with a machine-readable optical label of different black squares arranged in a large square or rectangular grid. When scanned, the bar codes respond quickly to allow access to its embedded information about the item to which it is attached.

Service Providers: A term used to refer to a whole range of agencies, organisations and institutions that provider services to the public (individuals and communities).

P

Political Context Elements in Public Policy of Radio Frequency Information Technology and Electromagnetic Fields

Joshua M. Steinfeld

Old Dominion University, USA

INTRODUCTION

A pinnacle in e-governance was reached with the development of information systems that utilize radio frequency technologies. For example, Radio Frequency (RF) towers' capabilities as communication and monitoring devices enable efficiency maximization and real-time solutions. Also, Advanced Imaging Technology (AIT) allows for quick and reliable information processing for purposes of tracking and surveillance. There are several advantages to government's use of Radio Frequency Information Technology (RADFIT) such as the ability to quickly communicate across a wide range of global positioning systems, management of communication portals, and survey of visitors entering secure environments in the case of millimeter wave scanning.

The main issue with the presence of radio frequency electromagnetic fields (RFEMF) is balancing the benefits provided from supporting the RADFIT systems with the environmental effects of electromagnetism. Regulation of technologies is controversial as agencies and stakeholders struggle to weigh benefits and costs. Hood et al. (2001) presents a framework for understanding regulatory policy domains by classifying benefits and costs of Information Technology (IT) sciences according to competing political systems: interest group, entrepreneurial, client, and majoritarian. The interaction of these political context elements influences the corresponding regulatory regimes, which are ideographs that describe the track of reasoning of RADFIT systems consumers, producers, and regulatory bodies. By examining

regulatory regimes of the RADFIT sphere, public policy implications and future research directions emerge that may improve participatory confidence and informational effectiveness while mitigating threats to communities.

The main purpose of the manuscript is to discuss political context elements and their impact on the public policy arena surrounding RFEMF issues, in addition to touch upon organizational initiatives and public management alternatives. Political context elements of regulatory regimes are presented first. According to the *interest group* political system, incrementalism and the status quo are introduced as encumbrances to policy change. Lack of organization in the public policy arena limits viable alternatives and contributes to government lethargy. The *entrepreneurial system*, indicative of rational choice and new public management, is subsequently discussed as the prompt and elicitor of RADFIT solutions. Modernism and progression serve as societal themes that steer entrepreneurialism in IT and public sector activities in general. Next, the *client system*, which involves administrative responsibility, is highlighted as the regime offering the most potential for bureaucratic discretion and inquiry. The opportunities for interaction between regulatory agencies and resident stakeholders, creates inconsistencies and marginalization of particular societal participants. Then, the *majoritarian system*, serving as the basis for democratic forms of governance, is detailed so as to review the unresolved paradoxes involved in representative decision rules such as voting. Subsequently, organizational and community leadership initiatives, despite the obstacles posed

DOI: 10.4018/978-1-5225-2255-3.ch581

by political context elements, are illustrated to show the current state of organized opposition to RADFIT proposals. Recommendations and areas for further research follow in an attempt to consolidate diffuse community efforts.

There are several objectives of this entry. The controversy over RADFIT solutions is examined to explain how political context elements dictate regulatory regimes of the RFEMF sphere. This entry aims to provide an overview of the bureaucratic considerations underlying RADFIT guidelines and public policy as well as the response by communities. Public administration theory and recommendations for future action serve to provide frameworks for additional policy analysis. The goal is not to provide a comprehensive review of the RFEMF regulatory arena but instead to illuminate indicators that create the onset and resonance of various regulatory regimes, or ideographs, that dictate the decision-making of public policy participants of RADFIT applications including RFEMF, along with implications for communities.

BACKGROUND

There are millions of RF tower base sites in the world. The United States alone has more than 301,779 radio frequency tower and transmission base sites (Cellular Telecommunications Industry Association, 2013). In many cases the towers stand from 50 feet to 200 feet tall. RF base sites also exist in the form of small individual devices less than 2 feet by 1 foot in size that may be mounted on building roofs or siding. Broadly, the United States Department of Commerce identifies several objectives for the use of the radio spectrum and RFEMF to carry out national policies and achieve national goals such as national security, safeguarding of life and property, support crime prevention and law, foster conservation of natural resources, provide for dissemination of information and entertainment, promote research and exploration, stimulate social and economic

progress, and generally improve the well-being of man (National Telecommunications and Information Administration, 2014: Chapter 2). More specifically, several areas of strategic interest are identified according to these objectives including agriculture, consumer expenditures and saving, education, health, oceanography, public safety, outer space, social welfare, transportation, and urbanization (National Telecommunications and Information Administration, 2014: Ch. 2).

At the local level, by 2011, automatic license-plate readers were utilized by about three-quarters of police departments surveyed (American Civil Liberties Union, 2013), with civilian uses of license-plate readers emerging (Hardy, 2014). Commercially, retailers employ companies that track shoppers through cell phones in order to identify return shoppers and learn about other shopping habits or patterns while in the store for the purposes of improving store layouts, marketing, and overall profitability (Clifford, 2013a; Clifford, 2013b). In turn, government enjoys larger tax receipts from the increases in purchases that result.

The RADFIT data collected is transmitted, stored, processed, and analyzed at data centers. These large warehouse-type buildings house servers and hard-disk drives that sit on concrete slabs as large as several football fields and are typically located in rural areas where power is less expensive (McLellan, 2013). There are over 6000 data centers in the world with more than half in the U.S.; each data center consumes the amount of power equivalent to a city with 20,000-40,000 residents (President's Council of Advisors on Science and Technology, 2014, p. 30).

The environmental effects of RF tower bases have been of concern to community residents and researchers alike. For example, RF tower installation at public schools has been strongly opposed by various community voluntary initiatives and political activist groups (Steinfeld, 2013). Similar to the RF towers that utilize RFEMF technology, AIT scanners are commonly used to scan subjects entering secure areas. In May 2013, the Transpor-

tation Security Administration (TSA) disposed of approximately 800 Rapiscan full body scanners, called “puffer” machines, due to concerns regarding irradiation of subjects (Jansen, 2013). Millimeter wave imaging systems replaced the puffer machines and function by emitting radio frequency electromagnetic waves (RFEMW) in the millimeter spectrum (30-300 gigahertz) to render images that look like photographic negatives (Elias, 2012). As of September 2012, TSA deployed about 700 AIT scanners, or Whole Body Imagers (WBI), with plans to have a total of 1800 in use by 2014 (Elias, 2012).

One major issue with the systemic use of RADFIT and the immersive presence of EMF in society has to do with health concerns that have been cited in scientific studies, concluding that RFEMF can be dangerous to human health. Golbach et al. (2015) conduct a study of immune cells, in which it was concluded that exposure to LF EMF enhanced neutrophil extracellular formation, which leads to increased antimicrobial properties and damage to surrounding cells, essentially damaging the immune system. Additionally, Pall (2015) reviews 18 epidemiological studies in concluding that exposure to microwave and radio frequency EMF from cell/mobile phone bases trigger widespread neuropsychiatric effects such as depression, sleep disturbance, headache, fatigue, concentration dysfunction, memory changes, irritability, restlessness, and loss of body weight. Manzella et al. (2015) also determine that EMF affects the human biological clock. Pall (2015) reviews 6 studies that conclude radio and television antenna may have the same effects.

Differently, Shi et al. (2014) use in-vitro isolation techniques to test the effects of intermediate wireless magnetic fields and report no genotoxic effects from exposure. Furthermore, Shirai et al. (2014) recorded no significant negative impacts on the brain function of three generations of rats that were exposed to cell phone radiation for 20 hours per day. Yet, Du et al. (2014) report that

obese mice lose weight and fat when treated with direct current electromagnetic fields. Laramee et al. (2014) detected an elevation of heat shock gene expression as a result of static magnetic field exposure, indicating that RFEMF heat-up or “cook” its subjects. Lerchl et al. (2015) conclude that the number of tumors in the lungs and livers of animals were higher, in addition to elevated numbers of lymphomas, than in the sham-exposed group. The tumor producing effects are attributed to metabolic changes due to EMF exposure (Lerchl et al., 2015).

Without the hindsight of the recent scholarly literature and experimental studies on RFEMF, on January 3, 1996, the Federal Communications Commission (FCC) passed the Telecommunications Act “to promote competition and reduce regulation in order to secure lower prices and higher quality services for American consumers and encourage the rapid deployment of new telecommunications technologies” (Telecommunications Act, 1996). According to Section 332(c)(7)(B)(iv), “No State or local government or instrumentality thereof may regulate the placement, construction, and modification of personal wireless service facilities on the basis of the environmental effects of radio frequency emissions to the extent that such facilities comply with the Commission’s regulations concerning such emissions.” In conjunction with this limitation, Section 214(e)(1)(a) grants telecommunications carriers eligibility to provide their own telecommunications facilities in areas designated as “universal service,” even if a competitor is already providing wireless service coverage for the area (O’Neill, 1999).

Section 253(a) reinforces carriers’ rights in citing “No state or local statute or regulation, or other state or local legal requirement, may prohibit or have the effect of prohibiting the ability of any entity to provide any interstate or intrastate telecommunications service.” Incidentally, the Telecommunications Act may be in violation of fifth and tenth amendment Constitutional protections.

The fifth amendment, states that persons cannot “be deprived of life, liberty, or property, without due process of law,” and the tenth amendment declares that “The powers not delegated to the United States by the Constitution, nor prohibited by it to the states, are reserved to the states respectively, or to the people” (U.S. Constitution, 1789).

For AIT, Sections 101 and 109 in the Aviation and Transportation Security Act of 2001 provide for federal government’s authority to utilize RADFIT. Section 101(f)(8) makes it lawful for TSA to “identify and undertake research and development activities necessary to enhance transportation security” and Section 109(a)(5) provides for the lawful use of wireless technologies to aid in passenger screening (Aviation and Transportation Security Act, 2001). However, privacy issues related to AIT surfaced and thus Automated Target Recognition (ATR) technology was developed as an alternative means of security scanning (Elias, 2012). Essentially, WBI were transmitting and recording images of users, creating privacy issues since RFEMF pass right through clothing. Privacy-enhancing morphological edge and gradient detection software algorithmic technology was subsequently developed for millimeter wave scanners to combat the issue of privacy through distortion of facial and other physical features (Cavoukian, 2009), effectively silencing AIT opposition founded upon the privacy issue.

The lack of concrete experimental data on health effects of RADFIT and shortage of innovative remedies to combat health concerns has brought into question the impact of invisible risks posed by RFEMF. Meanwhile, the Telecommunications Act has authority over local and state powers but may in fact be unconstitutional. Consequently, public policies governing RADFIT are being inconsistently applied and the regulatory environment remains ambivalent. With the failure of public management to achieve universal clarity and resident support on issues such as rights-of-way, regulatory stances continue to be conceded by political elements.

POLITICAL CONTEXT ELEMENTS AND VOLUNTARY INITIATIVES

P

Interest Group Politics

The confrontation between advocacy coalitions representing competing interest groups leads to incrementalism and the status quo. As a result, it becomes unlikely that current trends in RF tower base proliferation or use of RADFIT solutions for communicative and security applications will be curtailed. There is a status quo and changing it requires special justification (Baumgartner et al., 2009). The main issues such as whether or not to allow RF towers to be erected near schools and residential neighborhoods, or if AIT systems should be required for entry into secure areas have been at deadlock since the major benefits of RADFIT were discovered and capabilities implemented. Additionally, the interest group narratives have largely remained unchanged. For example, the American Cancer Association (ACA), a federal funding beneficiary, continues to maintain that scientific evidence has not conclusively indicated that electromagnetic fields created by RF towers and other base sites are hazardous to human health due to the longer wavelength of RF and its lower energy level as compared to gamma rays or x-rays (American Cancer Society, 2013). Meanwhile, opponents to RFEMF have advocated a not-in-my-backyard approach to RF towers and employed bounded rationality when dealing with RADFIT security apparatuses.

Bounded rationality emphasizes the cognitive limitations of decision-makers and is the arbitrary underpinning of the advocacy coalition approach (True et al., 2007). Health hazards from RFEMF absorption, an invisible risk, remain disputed. From consumers and producers’ perspectives, the idea of losing mobile connectivity from absence of RF towers or being susceptible to security breaches and inefficiencies by avoiding utilization of AIT systems is tangible. Jones (1994) argued that decision changes do not arise from changes

in preferences or irrationality; they emerge from shifts in attention called “serial shifts.” The senses process information equally but attention is serially committed to one idea at a time (Simon, 1983). The dominant, or tangible concerns, as opposed to the invisible health risk, occupy the psyche. Typically, only one primary aspect of the choice situation serves as the critical decision factor (Simon, 1957, 1985; Zaller, 1992). As a result, both individual and tactical initiatives seeking to oppose RADFIT applications are lulled by even the supporters who share the utmost concern and consciousness over the issue. The status quo is maintained and incrementalism persists through steady growth of RADFIT applications as new technologies that create efficiencies.

Entrepreneurial Politics

New public management and undertones of progressivism continue to guide bureaucratic conduct in lieu of rational choice logic. While rational choice theory has been founded upon the notion that market mechanisms should be used to settle collective choice problems (Hill, 2009), as in the case of new public management (Hood, 1995), a core competency of any sound public policy involves the conception that public value is being created for society (Moore, 1995). In the case of RADFIT applications, the benefits of utilization are real and the potential costs associated with health risks are hypothetical. Meanwhile, remnants of Wilson’s (1887) progressive movement continue to trigger the cogitation of clever solutions to microcosmic issues that could have been left unresolved, such as in the case of AIT as a solution to laborious manual screening.

Rational choice, in the form of economic individualism, has become a decision rule under the new public management accordance in bureaucracy, enticing public leaders and the public at large to look to the private sector for solutions and then to the government and nonmarket institutions upon market failure (Bozeman, 2007). For example, public agencies purchase AIT ap-

paratuses in place of hiring trained workers and corporations are placated by political authorities with permissive jurisdiction that enable RF tower producers to enjoy productive economies of scale with RF tower construction and maintenance. Without major indication of widespread epidemic from RFEMF exposure and documented incurrence of costs, the entrepreneurial policy domain continues to be dictated by technocratic principles of automating bureaucratic processes.

Consumers of RADFIT applications are similarly limited in scope by rational choice decision-making as it relates to social exchange and public choice theory. Under the auspices of social exchange theory, people choose courses of action that yield the least amount of blame and will behave differently based on the number of people present (Latane & Darley, 1970; Heath, 1976). Users of RFEMF are unlikely to dissent if numerous bystanders are present in the case of AIT screening or a large number of people stand to lose through loss of wireless services. Instead, users exercise public choice and abide by laws of collective action. Policy change advocates have a common interest in benefits but are unwilling to incur the costs of providing the collective good (Olson, 1965). Miller (1994) attempts to cast doubt on social exchange and public choice theory through witness of periodic altruistic behavior. Considerately, policy entrepreneurs tend to thrive from outside their formal positions of government or participative roles (Roberts & King, 1991); there is no opportunity, or policy stream (Kingdon, 2008), for advocates of regulatory change to act extemporaneously or institutionalize concerted efforts, respectively.

Client Politics

While dangers to human health and wellbeing may be natural and inevitable, the exacerbation or mitigation of risks, and how costs are disbursed, are not (Minow, 2012). Public administrators are oftentimes in tension with the citizenship role, creating potential for recurring conflict between

the two identities (Cooper, 2012). The extent to which public administrators are responsive to challenges or remain responsible to the bureaucracy is determined by client politics. Bureaucrats with knowledge-in-the-process (Lasswell, 1970), those administrators involved in RADFIT solicitation and implementation, are bound by characteristics of bureaucracy. For example, government or contracted operators and repair personnel of potentially hazardous RF hardware fail to express health and wellbeing concerns because current tasks are thought to be temporary given hopes of ascending in rank or being delegated task variation, even though the position continues to be in existence and held by another incumbent nonetheless (Weber, 1946). In this case, the public administrator or contractor is a client of the bureaucracy, furloughed by self-interest (see Downs, 1967; Dunleavy, 1991).

Oppositely, Weber (1947) and Fayol (1949) posit bureaucracy as client-oriented and administrators as bureaucratic servants that subordinate individual interest to general interest and create a division of labor with clearly defined responsibilities. According to this rigid structure, RF tower and AIT technicians and operators employed by the government are unlikely to ever converge with clients that are external to the bureaucracy, such as concerned subjects of RADFIT applications. In accordance with Weberian traditionalism, public administrators cling to old ways despite individuals' tendency to be progressive in other spheres of life (Manheim, 1936). Public administrators and technical experts become mesmerized with current innovative capacities instead of embracing advancement in thought, thereby neglecting ideological evolution (Burke, 1790). Soon thereafter, the bureaucrat is unable to retrospectively imagine society without a propagation of RF towers or reliance on AIT machines.

Majoritarian Politics

The calculus supporting denunciation of majoritarian politics has been aptly applied over the course of policy domains (Arrow, 1951; Buchanan &

Tullock, 1962; Tullock & Wagner, 1978). From a regulatory standpoint, the economic-type limits to control, *de minimis non curat fiscus*, parallel downfalls of majoritarian decision rules (Hood, 1976). For instance, bureaucrats may simply lack the authority to impact implementation and utilization aspects of RADFIT components and systems, a control that could rest with a few policy makers and loitering advocacy coalitions. In other cases, colossal consumer markets welcome RADFIT solutions that promise to create even more wealth for government and societal members. The economic and ideological grandeur of RFEMF applications circumscribes the eclipsing echoes citing dangers to RF absorption.

Other modes of majoritarian politics take shape through consumer federalism (Wildavsky, 1998). When one AIT model is found to be ineffective or believed to be exceptionally hazardous to users' health, as in the case of "puffer" security scanning machines, then it is possible for consumer federalists to play off one producer against another in order to pursue agency procurement ambitions. Governmental consumers and RFEMF regulatory bodies achieve cohesion as a spectrum emanates for the devices market through not only determining the lawfulness of the technology but also devising a range of acceptable exposure restrictions. Davis, Dempster, & Wildavsky (1966) identify these decision rules as the deviant case and shift point. The deviant case involves the underlying controversy over RADFIT solutions whereas the shift point rests along the spectrum of technological capacity. These decision rules are non-incremental and therefore typically exist in a state of stasis, left to coagulate solely according to further advancements.

Voluntary Initiatives

Despite the unfavorable political context elements that present obstacles to effective regulation of RADFIT, numerous initiatives have surfaced that contribute to regulation of RADFIT and EMF. The European Union, on November 14, 2011, was the first organization to ban use of "backscatter" ion-

ized radiation technology in favor of millimeter wave scanners (DiSalvo, 2011; Jaslow, 2011). Additionally, the International Association of Fire Fighters officially opposes the idea of mounting RFEMF applications on firehouses until further research (International Association of Firefighters, 2014). In Australia, community groups have succeeded in organizing at the national level through a group called No Towers Near Schools that provides support and information on current disputes around the country (No Towers Near Schools, 2014). Elsewhere, community leadership efforts have spanned international borders. On December 1, 2013, more than 100 people in Tsawwassen, Canada and 200 people in Point Roberts, U.S. protested near the border, on 1st avenue and 56th street, vowing to stop the installation of five towers that would affect residents on both sides (Hager, 2013).

In the U.S., there are dozens of communities in California currently organizing to reject RF towers such as in San Diego (see Verdin, 2014), Los Angeles (see City of Huntington Beach, 2013; West San Pedro Neighborhood Alliance, 2014; Northwest San Pedro Neighborhood Council, 2009), Carmel (see Arcega-Dunn, 2014), Hillsboro (see Lee, 2013), and San Rafael (see Upshaw, 2009). The presence of EMF base sites has also garnered substantial attention in New York, as an example, where the Department of State released the publication entitled *Planning and Design Manual for the Review of Applications for Wireless Telecommunications Facilities*. Governor Andrew Cuomo believes that municipal regulation of cellular phone towers and antennas is one of the most controversial and heavily debated current local government land use issues (Legal Memorandum LU01, 2014). Similarly, the North Carolina League of Municipalities released guidance on the current tensions between wireless service providers' desire for an efficient, streamlined, predictable, and expedited regulatory process as opposed to citizens' desire for transparency and interest in maintaining rights inherent to democratic opposition (Hibbard, 2013).

SOLUTIONS AND RECOMMENDATIONS

New approaches to policy change are required if regulatory regimes in the RFEMF sphere are going to be expanded or added to. Currently, there is rapid promulgation and application of RADFIT solutions given the apparent stalemate within political context elements. Unchallenged RFEMF base sites vastly outnumber community leadership initiatives. Baumgartner & Jones (1993) found that policymaking leaps and periods of stasis share a tendency toward punctuated equilibrium, or unforeseen impulse; an unfavorable regulatory outcome whether it results in health epidemic, extreme loss of connectivity, or security breach.

Solutions to static regulatory environments can be found by emulating the postmodern movement. Stivers (1994) emphasized bureaucratic listening as a way to compensate for spatial differences between stakeholders in regulatory settings. Regulatory agencies have neglected the wide body of research conducted that implicates RFEMF technology as hazardous. However, it may not be critical for the policy change initiatives to rest with empirical conclusions where validity and reliability remain controversial. Miller (2013) builds on postmodern approaches to public policy and administration through examination of ideographs. The narratives that produce symbolic images of policy domains have the potential to bypass the empirical struggle plaguing the certainty of RFEMF research. Scientific reference may be replaced by ideographs that portray RF towers as nuisances, eyesores, or institutional threats to privacy. The very notion of empirical uncertainty may emerge as a lasting narrative that paints ideographic imagery similar to that of the questioned invisible risk such as viable slogans that could include "you can't regulate what you can't see" and "go easy with radiofrequency."

According to new public management, a counterpart to postmodernism, narratives of efficiency, cost-effectiveness, capacity building, and innovation serve as underpinnings for policy implementa-

tion, yet creativity remains through mobilization such as outsourcing. The Telecommunications Act of 1996 aimed to expedite telephone carriers' efforts and conserve their vital resources while striving to provide resident, business, and government consumers with affordable and "universal service." In *Reinventing Government* (1998), Osborne and Gaebler argue that government "steers rather than rows," which is exactly what the federal government did by contracting out telecommunications infrastructure, services, and maintenance to private companies while at the same time providing authoritative means with regards to competition, site placement, and procurement (Telecommunications Act, 1996). Instead, government should "serve rather than

steer," whereby public servants help citizens articulate and meet their shared interests rather than steering society to new directions (Denhardt & Denhardt, 2000).

Local and state governments may help communities to consolidate their efforts so that advocacy can be directed to federal government action. An amendment to the Telecommunications Act is required to consider health effects and unsightliness of RADFIT. Under the revision, Title 47 of the Code of Federal Regulations needs to be specifically added to Section 332(c)(7)(B)(iv) of the Act (Table 1). Federal limits for Maximum Permissible Exposure (MPE) to radiofrequency radiation clearly state that exposure by the general public is not to exceed 30 minutes.

Table 1. Title 47: U.S. code of federal rules

Code of Federal Rules				
Title 47: Telecommunication				
Volume: 1				
Date: 2011-10-01				
Title: Section 1.1310 - Radiofrequency radiation exposure limits.				
Context: Title 47-Telecommunication. Chapter 1-Federal Communications Commission.				
Subchapter A- Part 1. Practice And Procedure.				
Subpart I-Procedures Implementing the National Environmental Policy Act of 1969.				
Frequency (MHz)	Electric Field (V/m)	Magnetic Field (A/m)	Power (mW/cm2)	Time (mins)
Limits for Occupational/Controlled Exposures				
0.3-3.0	614	1.63	*100	6
3.0-30	1842/f	4.89/f	*900/f ²	6
30-300	61.4	0.163	1	6
300-1500			f/300	6
1500-100,000			5	6
Limits for General Population/Uncontrolled Exposure				
0.3-1.34	614	1.63	*100	30
1.34-30	824/f	2.19/f	*180/f ²	30
30-300	27.5	0.073	0.2	30
300-1500			f/1500	30
1500-100,000			1	30

Occupational/controlled limits apply in situations that persons are exposed from employment.

General population/uncontrolled exposures apply in situations that the general public is exposed.

f = frequency in MHz

* = Plane-wave equivalent power density

Therefore, RF towers that are mounted on or adjacent to schools, buildings, parks, neighborhoods, playing fields, or other sites may technically be rejected due to excess general population/uncontrolled exposure beyond 30 minutes. However, a strong lobby exists that demands connectivity, and connectivity cannot occur without exposure; it is the presence of RFEMF that enables RADFIT. It is unlikely that community voluntary initiatives will have the impact of freezing RADFIT expansion or destructing current base sites. However, base sites that are opposed by communities should be rejected or removed if already in place and a federal mandate is necessary to achieve equality on this matter across all stakeholder communities.

FUTURE RESEARCH DIRECTIONS

Hood and Margetts (2007) see the future as an extrapolation of the past; the tools of the digital age may create heightened levels of nodality such as cyber detection and group targeting. While rapid installation of RF towers and continued usage of AIT devices will increase the number of systems users and the overall outreach of RADFIT application, it is unlikely that growth alone in the number of RF towers or AIT devices would increase nodality; advancements in RFEMF capabilities would likely be required. Furthermore, RADFIT enhancements may be met with incremental policy challenges as regulatory regimes gradually shift according to new research developments. Unfortunately, consumers and producers are forced to continually exercise a responsive-type of policy influence, as new technologies can typically be more quickly implemented than empirically deemed to be unsafe. Meanwhile, there is immense competition between researchers seeking to conduct progressive research on RFEMF utility and those experimenters aiming to uncover any negative externalities associated with RADFIT systems.

RFEMF research has been conducted on rats and human organelles. Research on rats is largely

conclusive in determining toxic effects of exposure. Yet, rats are much smaller mammals than humans and are not viewed to be similar by the general public. On the other hand, research on humans that could involve immense danger to human subjects is not feasible and there would be significant challenges to securing a control group in any case, given the numerous factors that can affect human health over the course of a study, especially if long-term effects of RF absorption are the foci of study. Nonetheless, the intrusive placement of many existent RF towers provides an opportunity for surveying human subjects, especially if the RF towers are not going to be removed.

Furthermore, expansive environmental impact studies need to be conducted to ascertain the broad impact of RADFIT. On September 14, 2000, the U.S. Department of Interior, on behalf of the Fish and Wildlife Service, issued a cautionary statement of RF towers' impact on migratory birds. A Communication Tower Working Group consisting of government agencies, industry, academic researchers, and non-governmental organizations was formed by the Service to reduce the estimated 4 to 5 million bird deaths per year that occur from colliding with communication towers (Clark, 2000). It may be possible that RFEMF has physiological effects on birds as well. In either case, birds' migration is being obstructed which could influence other animals. Impact studies of communication tower base sites and isolated RFEMF on living organisms within complex ecosystems would advance the field's body of knowledge.

For now, the precautionary principle is suggested for dealing with the regulatory sphere of RADFIT and EMF. Previously, the precautionary principle has been advocated for application to regulatory decision-making regarding sustainable development including the Rio Convention and Kyoto Protocol (Steele, 2006), and it is now being recommended when it comes to government's regulation for the use and power of electromagnetic fields (Portier, 2015). The precautionary principle involves employing alternatives in situations when

irreparable health or environmental risk may result from a particular action while the research is inconclusive or not yet realized in terms of the risks. Considering the set of feasible alternatives determines whether the actions of independent agents need to be restricted given certain levels of risk to the environment and human health (Tickner, 2003).

CONCLUSION

Expansion and application of RADFIT solutions continues to progress at a rapid pace. Empirical research regarding health effects from RFEMF absorption are surrounded by controversy and lag behind innovation. Currently, the four major political context elements and respective bureaucratic limitations of the regulatory environment results in public policy stasis. Interest group politics have contributed to incrementalism and the status quo while at the same time entrepreneurial modes of political will are defeated by deficiencies inherent to economic individualism and social exchange. In addition, client politics posit the public administrator as a participant nullified by dual roles as bureaucrat and resident client, just as majoritarian approaches to decision rules are malignantly constructed along a spectrum that serves to favor strategic public procurement of RADFIT devices.

Modernism and progression have dominated the narrative platform to date. Bureaucratic listening and postmodernism in the form of ideographs serve as communicative devices that can be used by community organizations to minimize the stakeholder gap between users, consumers, and producers of RADFIT systems. Reform of the Telecommunications Act and consolidation of community leadership initiatives are concrete solutions. Given the propagation of RFEMF infrastructure, empirical studies using survey data of residents living near RF towers or frequently exposed to other AIT devices is logical and does not contribute additional threat to subjects already experiencing continual RF absorption. Irrespective

of health concerns related to RFEMF and RADFIT solutions, sociological constraints remain that are detrimental to the contributions of individual stakeholder and regulatory participants.

KEY TERMS AND DEFINITIONS

Advocacy Coalition: A group of like-minded policy participants and stakeholders that seek policy change through lobbying and communication with policy makers.

Bounded Rationality: The cognitive limitations of decision-makers and the arbitrary underpinning of the advocacy coalition approach.

New Public Management: An emphasis on privatization and outsourcing in order to maximize profitability and optimize resource allocation.

Postmodernism: A new consideration in public administration that tends to ignore productivity and profitability constraints in favor of more humanistic indicators of preference.

Public Choice Theory: A theoretical proposition that explains policy participant and stakeholder hesitancy despite shared common interests.

Rational Choice: Policy analysts make decisions that maximize public value while minimizing the cost of such benefits.

Risk Regulation Regime: Ideological and narrative underpinnings of the regulatory framework governing specific public policy issues.

Social Exchange: The notion that stakeholder behaviors change according to the situational context such as the number of bystanders present.

Stasis: Public policy issues reach a stalemate where the political context elements underlying risk regulation regimes are unable to influence effective policy change.

Public Policies for Providing Cloud Computing Services to SMEs of Latin America

Mohd Nayyer Rahman
Aligarh Muslim University, India

Badar Alam Iqbal
Aligarh Muslim University, India

INTRODUCTION

SMEs are an integral part of the Latin American Economic Region as they represent 99% of all the businesses and account for around 67% employment (LACFORUM, 2013). Thus, SMEs are the backbone of the Latin American economic region: a region characterised by high aspirations of the people towards trade and development. Since times immemorial governments are trying to boost the performance of SMEs due to their power of generating domestic employment. In the present world of technologically advanced operations, there is huge potential in SMEs to contribute towards the development of the region. Challenges are posed by the MNCs in the same region or the ones entering the region. MNCs are characterised by the use and employment of technologically sophisticated method of manufacturing and operations. Apart from this MNCs are also interested in R & D activities and widely invest in R & D department for improving efficiency in order to gain economies of scale. They benefit from the use of IT enabled services to increase the efficiency of the business. For managing knowledge, MNCs widely use cloud computing services provided by specialised companies. Cloud computing has been used as a tool by which ITES can be utilised by firms and it can help in better economical and operational decision making. SMEs of the Latin American economic region too aim for

increasing efficiency and optimising the use of ITES. Cloud computing will empower the SMEs of Latin America to compete with the MNCs. Cloud computing as a modern concept under felicitation of business by adding value to the business and operations achieving cost efficiency in the business. If SMEs of the Latin American economic region are provided cloud computing services through policy initiatives, it would not only add value to the SMEs businesses but also will increase the sustainability of the economic region. Cloud Computing is an opportunity to utilise shared resources for optimising business operations in the technologically driven global economic environment. Typically, cloud computing services include access to databases for the businesses, access to software that is important for decision making and contribution to knowledge and information sharing. Cloud Computing aims to reduce the amount of complexity, minimise costs, and enhance organisational agility (Ghaffari et al, 2014). Cloud Computing decreases the obstacles to conducting information process intensive activities. Indeed, people do not need to maintain their own technology infrastructure as they transfer the burden of system management and data protection to the cloud computing service provider (Jeager et al, 2008). Thus, the study will focus on the issues related to the formulation of public policies for providing cloud computing services for SMEs of Latin America.

BACKGROUND/CONCEPTUAL FRAMEWORK

Cloud Computing

It involves the use of appropriate hardware and software along with networks that allow centralised data storage and online access to the same. It also includes free or restricted (depending on the political and economic environment of a country) access to computer services and resources. Its aim is to achieve economies of scale and coherence by sharing knowledge resources. The term cloud is used as a metaphor for a setup both tangible and intangible that is a collection of tools and resources related to IT-enabled services. With cloud computing services, a business can optimise both its operations and decisions as more easy and fast sharing of knowledge is possible. Cloud Computing is a set of services that provide infrastructure resources using internet media and data storage on a third party server.

Cloud Computing comprises of three services:

1. **Software-as-a-Service (SaaS):** Under this, particular service software is provided online for the consumption of the end user. It stands in opposition to the purchase of the software and then regular updates by the client businesses. The prominent software under this category are applications like Word Processing, CRM (Customer Relationship

Management), ERP (Enterprise Resource Planning) etc. This is a matured model and through it, businesses can achieve economies of scale. Commercial vendors include Yahoo mail, Gmail, Hotmail, TurboTax Online, Facebook, Twitter, Microsoft Office Live, Google Apps, Cisco WebEx conferencing etc.

2. **Platform-as-a-Service (PaaS):** Under this service, software development kits and tools are provided on platforms. The tools include Java, NET, Python, Ruby on Rails. Prominent commercial vendors include Microsoft Azure Services, Amazon Web Services (AWS), Salesforce, Google App Engine Platform, IBM Cloudburst, Amazon's relational database services, Rackspace Cloud Sites etc.
3. **Infrastructure-as-a-Service (IaaS):** This refers to devices such as storage devices, servers, virtual computers, network transfers etc. which are physically located in one central place which is known as data centre but they can be accessed and used over the internet from anywhere using the login authentication systems.

Within organisations there are different cloud deployment models such as:

1. **Public Cloud:** Easily and economically available from a third party provider via

Figure 1. Service model of cloud computing

Table 1. SME definitions used by multilateral institutions

Institution	Max. of Employees	Max. Revenues/Turnover (\$)	Max. Assets (\$)
World Bank	300	15000000	15000000
MIF-IADB	100	3000000	None
African Development Bank	50	None	None
Asian Development Bank	No official definition/ Individual national definition used	No official definition/ Individual national definition used	No official definition/ Individual national definition used
UNDP	200	None	none

Source: Gibson & Vaart, 2008, Brookings Global Economy and Development

- internet for deploying IT solutions. The famous example is Google Apps.
2. **Private Cloud:** It is suitable for large organisations and remains within organisations. The US government cloud product (Federal Information Security Management Act) FISMA certifies such clouds and is being handled by a third party provider e.g. Google Private Clouds.
 3. **Community Cloud:** It is used and controlled by a group of enterprises that have shared interests in the cloud computing services e.g. US Federal government is using cloud community such as forms.gov, file.gov, cars.gov, USA.gov, Apps.gov.
 4. **Hybrid Cloud:** It is a combination of the public and private cloud.

Public Policy

Public policy refers to the administrative steps taken by executive branches of states towards a specific or a class of issues in a way that is consistent with the legal framework of the state. The aim of the strong public policy is to solve problems efficiently and effectively, serve justice, support governmental institutions and encourage active citizenship. In other words, the term public policy always refers to the actions of government and the intentions that determine those actions. The policy is a series of actions coordinated to achieve a goal. Three qualifications are necessary for public policy:

1. The idea of the intentional course of action stating not to take a certain action.
2. The requirement that official actions be sanctioned by law.
3. Laws should not be mistaken for the whole realm of the policy.

Small and Medium Enterprise (SMEs)

SMEs are defined differently by different organisations and countries. Their definition may be based on the size of the firm, revenue/sales/turnover, number of employees, access to international markets etc. Different definitions of SMEs as given by multilateral institutions are presented in Table 1.

Among Latin American countries there are at least two different definitions of an SME. One is based on the number of employees in the firm and the other uses sales revenue to determine the economic size of production units. The first definition ignores what was usually major differences among sectors (and among branches within each sector), often resulting in SMEs contribution to the economy being overestimated (LAEO, 2013). In Argentina and Chile, the two criteria have been used to estimate the difference between the official figures and the real figures. The results found that the official figure for the contribution of SMEs to the total number of the job was 7 percentage points too high in Argentina and more than 20 points too high in Chile (Stumpo, 2007). However, this is the criterion used in national

statistics departments, which often provide the data available in these countries, while the policy making bodies define company sizes based on the sales revenue criteria.

REVIEW OF LITERATURE

Several studies highlight the importance and need of cloud computing in general and few others in particular about the SMEs improvement through cloud computing. From a policy perspective very few studies are available on cloud computing but no such study in reference to Latin American SMEs is available. Authors have identified the paradigm shift in businesses due to cloud computing and have equated the transformation as analogous to the replacement of individual generators by the centralised electricity grid (Etro, 2011; Li & Wang, 2011). The development of cloud computing was captured as an opportunity by large enterprises throughout the world by adopting cloud computing bandwagon (Klie, 2011; Li et al, 2011; Walsh et al, 2011). But the decision has remained tough for the SMEs to decide whether to take cloud computing services or not and if yes up to what extent (Gupta, Seetharaman& Raj, 2013). Studies have highlighted that SMEs are a potential market for cloud computing and companies are ready to offer cloud computing services at fewer prices as compared to the same service provided to large corporations. The prime need of SMEs is software and other services that help them to manage emails, licensing to software's, other assets etc (Ferguson, 2008). King, 2008 has identified several points in relation to small businesses moving to cloud computing services such as IT infrastructure availability, minimal upfront investment, disaster recovery, software upgrades etc. Through this SMEs can reduce the cost of knowledge operations, potential avoidance of natural disaster mishaps but the fear is for reliability in using cloud computing services by the SMEs. In the study, King concluded that

SMEs are showing positive inclination towards cloud computing. The important cloud computing parameters that are looked by SMEs includes trust in cloud providers, incremental cost, and reliability. The benefits identified for SMEs using cloud computing services includes security, reliability, trust, cost reduction, online collaboration etc. The success of the cloud computing adoption by SMEs was discussed and it was concluded that SMEs can explore cloud computing with relatively little risk (Clark, 2009). It was observed and empirically searched that security and privacy are top concerns of 51% small and medium businesses. Other factors considered by SMEs includes availability versus sudden downturn and migration across cloud services. The importance of moving to cloud step by step was recommended using a couple of tips for SMEs and thus moving to cloud computing was strongly emphasised (Martin, 2010). The variables for adoption of cloud computing services by SMEs includes cost reduction (in terms of data storage, subscription, low upfront cost, cost control via scalability, elasticity of resources), convenience (easy usage in terms of accessibility and availability from anywhere and anytime), reliability (indicates dependability to use it whenever needed), sharing and collaboration; and security and privacy (Gupta, Seetharaman& Raj, 2013). Large number of authors have classified three services under cloud computing: Software-as-a-Service, Platform-as-a-Service and Infrastructure-as-a-Service (Mahesh et al, 2011; Sultan, 2011; TruongandDustdar, 2011; Ojala&Tyrvaainen, 2011; Creeger, 2009; Liet al, 2011; Durkee, 2010; Marston, Li, Bandyopadhyay, Zhang, and Ghalsasi, 2011; Karadsheh, 2012; Rath, 2012; Neves, Marta, Correia, and de Castro, 2011; McAfee, 2011). There has been no common standard or definition for cloud computing seems to exist (Grossman, 2009; Voas& Zhang, 2009). In the history of IT, the manner in cloud computing is providing elasticity of using resources without having to pay a premium for large scale investment is unprecedented in the history of IT (Armbrust et

Table 2. Cloud revenue (in billion dollars)

Region/ Country	2011	2014 (Estimate)	2016 (Estimate)	CAGR in %
Argentina	0.2	0.4	0.6	28.5
Brazil	1.4	2.7	4.4	25
Mexico	0.6	1.1	1.8	26
Other	0.2	0.5	0.8	26
Latin America	2.4	4.7	7.6	26.4

Source: Cloud Computing in Latin America, ECLAC-Projects Documents Collection, 2014

al, 2009). A research conducted by Easynet Connect showed that UK SMEs are increasingly eager to adopt cloud computing with 47% planning to do so within the next 5 yrs. Of those which indicated their preparedness to move to cloud computing, 35% of them cited cost savings as the key driver (Stening, 2009).

European Network and Information Security (ENSIA) in its survey found that 68% of the SME responses it received indicated that avoiding capital expenditure in hardware, software, IT support and information security is behind their possible engagement in cloud computing (ENISA, 2009). Sultan, 2011 concluded in its study that cloud computing is likely to be an attractive option for many SMEs due to its flexible cost structure and scalability. Weintraub and Cohen (2015). Attempted in their study to minimize the cost of Cloud Computing services provided to consumers. They came up with three models such as hierarchical, simple pricing model and the complete pricing model. In order for the price models to be effective, they also identified three pre-conditions and these will exteriorize in the long run. In another study, same authors reached to a conclusion that consumers of cloud computing services are attempting to maximize overall utility while encountering open tariffs. Bundling of Cloud computing services blocks market competition in cloud computing market (Weintraub & Cohen, 2015).

OPPORTUNITIES FOR PROVIDING CLOUD COMPUTING SERVICES TO SMEs OF LATIN AMERICA

It is of paramount importance to highlight the concept of cloud computing services in Latin America as one unit and then move on to build the linkages with the SMEs of Latin America. While building this discussion it must be kept in mind that no specific study is available on the current status of SMEs of Latin America with respect to cloud computing services. The cloud computing services usage is indicated by the revenue generated by the public cloud. The data for revenue is also scarce and is available only in few reports that too of one or two specific years. Thus, it remains difficult for the researchers to highlight the increasing use of cloud computing services. In the coming lines, that would be attempted with the help of data available.

Above mentioned Table 2 highlights the cloud revenue generated in Latin America as a sign of the increase in the use of cloud computing services. The figures for 2011 are real and for other years its estimated data. Argentina shows an increasing trend in the revenue collected through cloud computing services with a CAGR of 28.5%. On the other hand, Brazil and Mexico show CAGR of 25% and 26%, respectively. Both the countries also indicate an increase in the use of cloud computing services. Other countries (apart from Argentina, Brazil, and Mexico in the Latin American Region) also shows an increasing trend in the cloud computing revenues. Overall the Latin American region shows a CAGR of 26.4% which indicates potential opportunity in the future and is a clear indication that the users of cloud computing will increase. It would be justified to state that SMEs of the Latin American region can take benefit of this opportunity and can use cloud computing services. Figure 2 presents the data of Table 2 to highlight the present opportunities in Latin America.

Figure 2. Cloud revenue

Source: Prepared by author from Table 2 data

Figure 2 clearly shows that Compounded Annual Growth rate (CAGR in %) is promising for all individual countries as well as for the Latin American region. This may be extended towards the opportunities for SMEs for using the cloud computing services. Further, Table 3 highlights the important variables relevant to the cloud computing services in Latin America.

Elucidation of the details of Table 3 includes variables such as Cloud Traffic Growth, Data Centre Workload, Cloud Workload and Traditional Data Centre Workload. For the period 2013-2018, cloud traffic shows an increase of 35% as Com-

pounded Annual Growth Rate. The rate is high and shows that use of cloud computing services is increasing. The second variable, that is, Data Centre Workload is also increasing with a CAGR of 21%, again highlighting the increase in the use of cloud computing. The third variable, that is, Cloud Workload shows a whopping growth of 34% CAGR and aligns itself with the findings of above data. The final variable given in the table states that traditional data is showing a very slow rate due to the slow transformation in the devices used. New devices are now preferred by the users instead of old ones.

Table 3. Latin America cloud computing data

Variables	2013	2014	2015	2016	2017	2018	CAGR %
Cloud Traffic Growth (exabytes)	89	130	180	240	312	394	35
Data Center Workloads (millions)	2.6	3.2	3.9	4.7	5.7	6.9	21
Cloud Workloads (millions)	1.2	1.7	2.3	3.1	4.1	5.2	34
Traditional Data Center Workloads (millions)	1.4	1.5	1.6	1.6	1.7	1.7	3

Source: CISCO Visual Networking Index: Forecast and Methodology, 2013-2018

Table 4. Regional consumer cloud storage users by 2018 in Latin America

Consumer internet users in millions (% of population)	355 (55%)
Average number of devices per consumer internet user	3.87
Consumer Cloud Storage users in millions (% of internet users)	109 (31%)

Source: CISCO Visual Networking Index: Forecast and Methodology, 2013-2018

Table 4 highlights the estimate for 2018 about key variables that shows the use of cloud computing services. Consumer internet and cloud storage users, both will increase in the years to come. According to the estimate, 55% of the population will be using consumer internet services by 2018 in Latin America and 31% would be using cloud storage services. The average number of the device per consumer will also increase to 3.87. Remember that consumer here does not refer to individuals but the connections (where each connection is taken as a consumer). Respective data related to SMEs would be worth discussing. Table 5 highlights that data.

Table 5 highlights the impact of cloud computing services on SMEs growth and job creation by SMEs in Latin America. As estimated by ECLAC, beginning from 2013, in next 5 years (i.e 2014 – 2019) SMEs in Argentina can create 117300 jobs and number of SMEs will rise by 24700 due to the presence of cloud computing services. With respect to Brazil, the figures are 861000 jobs and 202100 new SMEs in the next 5 years. The estimated figures for the next 10 years are also promising and shows the strength of cloud computing towards SMEs in Latin America. In next 10 years, Argentina will have 30300 more firms

and 128900 new employees under SMEs due to cloud computing services in Latin America. In Brazil, in the next 10 years, the figures would be 402650 new SMEs and 945000 new jobs. This shows that cloud computing has the potential to boost SMEs in Latin America over the next decade. This opportunity must be tapped by the respective countries with the help of public policies.

PUBLIC POLICIES FOR CLOUD COMPUTING SERVICES

This section will be a formulation platform for policies that will boost the SMEs involvement in cloud computing services. Following policies are suggested:

- Improving Access to Cloud Computing Service:** The primary objective of the administrative and executive set up in Latin America should focus on improving access to cloud computing services to SMEs. While corporations are working strategically for this, the administrative initiative is important which can be in the form of another ICT revolution or a new phase of ICT revolution in the region. For this ECLAC must take strong initiatives that should include collaborating with the cloud computing service providers. As it has been stated earlier that corporations are ready to provide cloud computing services to SMEs at low cost as compared to large corporations, they must be taken into confidence for doing so at an accelerated pace. Regulatory bodies of the respective country under Latin American economic

Table 5. Cloud computing impact on no. of SMEs and job creation

	Firms (in 5 yrs)	Employment (in 5 yrs)	Firms (in 10 yrs)	Employment (in 10 yrs)
Argentina	24700	117300	30300	128900
Brazil	202100	861000	402650	945000

Source: Etro & Colciago, Cloud Computing, structural change and job creation in SMEs, ECLAC, 2013

region should assure SMEs of the benefits they may tap in future.

- **Improving Quality of Broadband Internet:** Many countries in Latin America have low fixed or mobile broadband penetration such as Honduras, Nicaragua, Paraguay, Guatemala, Bolivia etc. By improving the quality of broadband, cost efficiency can be achieved by the SMEs. In this regard, policies should be framed that target to increase the quality of broadband. The quality of broadband has a direct relation with devices used by the firms. The cost of installation of devices must be reduced by state sponsoring or making a purchase of cloud computing devices under the category of tax deductible expense. SMEs heavily relying on the use of cloud computing services must be considered as key players and their quality of broadband be accessed regularly.
- **Strong Legal and Regulatory Frameworks:** The reality is that, in many countries within Latin America, there is no strict legal or regulatory framework. At administrative level laws must be more stringent so as to provide safety and security to the cloud computing devices may not be misused. For this fiscal norms must also be adhered to. This will boost the confidence of SMEs towards cloud computing and they will also take benefits of cloud computing. SMEs, in general, are not aware of existing legal and regulatory framework related to cloud computing. The government of the respective country should take the initiative in training SMEs about the existing laws and regulatory framework. Changes in existing framework that may benefit SMEs must be considered by policymakers on a serious note. Step by step strategies should be adopted to universalise the legal framework in the Latin American economic region.
- **Service Level Agreements for the Private Provider:** The main concern for SMEs is about security and portability. Due to this SMEs are reluctant to fully migrate to cloud services. Private providers must be asked under regulations and cloud guidelines to follow service level agreements with SMEs and it should cover service adaptability, system security, and latency, service reliability, data security etc. This will act as a motivation for the SMEs to benefit from the cloud computing services. Strict regulation must be made for penalising the service providers in case of breach of the agreement. Presently, there is no clause of penalising the service providers. This will minimise any possible loss to the operations of SMEs and will not affect their working capital or operations negatively.
- **Ease of Use and Convenience:** SMEs must be motivated through policy to outsource their accounting and finance work to the cloud which will leave more time for SME executives to spend on strategic work and initiatives. Their move from PC-based accounting packages to cloud-based ones would be strategically beneficial as well as a source of cost reduction in operations. This will also allow avoidance of continuous hardware updates by SMEs thereby eliminating maintenance woes for utilising different machines. The cloud approach will thus eliminate administrative overhead and will permit access from any geographical location, any device, and from any organisation.

FUTURE RESEARCH DIRECTIONS

The data for cloud computing services is available only in a haphazard manner. No time series data or panel data is available for cloud computing

services across countries. Due to this reason, the present study has used only descriptive methodology. In future, the researchers should work on primary data and should come up with sharing of the cloud computing data so that statistical analysis is possible. On the availability of the panel or time series data, specific causality between cloud computing services and other macroeconomic variables may be identified.

CONCLUSION

In the end, it would be justified to conclude that SMEs play an important role in the Latin American economic region and cloud computing services will improve the operations of SMEs thus benefiting the whole region. The future of cloud computing services in Latin America, particularly for SMEs is promising and will increase both number of SMEs and employment opportunities. There is a need for policies in favour of SMEs to reap the benefit of cloud computing services and for the same policies must target the issues such as access to cloud computing services, quality of broadband, legal and regulatory frameworks, service level agreements and ease and use of convenience.

KEY TERMS AND DEFINITIONS

Cloud Computing Services: Services which provide the facility of data storage both offline and online. It is data storage on a virtual world platform.

Community Cloud: It is used and controlled by a group of enterprises which have shared interests in the cloud computing services.

Hybrid Cloud: It is a combination of the public and private cloud.

Private Cloud: It is suitable for large organisations and remains within organisations.

Public Cloud: Easily and economically available from a third party provider via internet for deploying IT solutions.

Public Policy: It refers to the administrative steps taken by executive branches of states towards a specific or a class of issues in a way that is consistent with the legal framework of the state.

Small and Medium Enterprises: Enterprises whose scale of production is relatively small in the economy.

Advancement and Application of Scientometric Indicators for Evaluation of Research Content

R**Tazeem Zainab***University of Kashmir, India***Zahid Ashraf Wani***University of Kashmir, India*

INTRODUCTION

The 20th century may be designated as the century of the growth and development of metric sciences (Kumar et al., 2009). There has been a tremendous development of metric based fields like Bibliometrics, Scientometrics, Librametrics, Technometrics, Sociometrics, Econometrics, Biometrics, Cybermetrics or Webometrics in this epoch.

Scientometrics can be considered as an analogous conception to bibliometrics. Scientometrics is a novel scientific field joining science and technology with information science and expending numerous mathematical, statistical, data mining techniques and procedures to measure and quantify scientific information. It can be perceived as a discipline of science that encompasses bibliometrics, informetrics, webometrics, librametrics and other metric sciences. As matter of fact, today when the phase of scientific and technological revolution is massive but funding resources are trifling, the measurement of eminence of research productivity is essential and acknowledged by many. The basic requirement is to endorse the progression of science as competently as possible, i.e. to in the best way upsurge the power/prize degree from the financing science (Fiala, 2013). The term scientometrics was introduced by Vassily V. Nalimov & Z. M. Mulchenko in 1969 as Naukometriya in Russian, meaning the study of the evolution of science through the measure-

ment of scientific information (Glanzel, n.d.). As per Tague-Sutcliffe (1992) Scientometrics is concerned with the quantitative facets of science. The focus of scientometrics as a discipline is the literature of science and technology. Price (1961, 1963) defines Scientometrics is a science about science. It offers numerous perceptions, representations, and practices to researchers that when functional in an academic field helps to understand its fundamentals, position, knowledgeable core, and probable forthcoming progress. Wilson (1999) indicated that everything that encompasses quantitative features of science of science, science communiqué and science policy are in the content of scientometrics. While defining the term Van Raan (1997) also accentuated the quantitative learning of science and technology. Vinkler (2010) defined that Scientometrics cannot be circumscribed within the circle of a scientific discipline. He widened the description as quantitative study of people, sets, materials and phenomena in science and their relationships. Further, he adds that scientometrics also covers various other aspects like practices of researchers, socio-organizational arrangements, administration, procedures, national economy. He also specified that Scientometrics could be foundation of statistics and also can indicate the policy in science like performance checking, research precedence assortment, science-society or science-economics relative scholarships. Wilson (1999) considers scientometrics as an organized

DOI: 10.4018/978-1-5225-2255-3.ch583

method to assess the past, present, and future progression of science as he believes that its origin is from the interest of trivial group of scholars in the subtleties of science.

BACKGROUND

The term “Scientometrics” was not noticed in Western scientific circles until it was translated into English. The roots of Scientometrics lie in the survey piloted by Galton in 1874 among 180 prominent scientists in Britain in order to measure, comprehend, and define the eminence of significant scholars and their potentials (Godin, 2006). Then in 1900’s James McKeen Cattell, the Psychologist and Editor of Science, enthused by Galton measured scientific growth by observation and classification. He offered two important facets of scientific output: quality (i.e. worth as adjudicated by peers) and quantity (i.e. production). After that, in 1926 Lotka’s mathematical model to estimate the frequency of author’s publication in a field, in 1934, Bradford’s distribution law for articles through a set of journals.. Further the outline put forth by Price (1961, 1963) regarding the historical evolution of science and Bernal’s (1939) theory of the social function of science, idea of sociology of science by and Merton (1968, 1973) provided a back bone to the development of the field. Finally in 1969 the field was given a comprehensive name “Scientometrics” by the Russian mathematician Vasilii Nalimov. In 1977, this area took a great leap when a maiden issue of Scientometrics journal by T. Braun was available, and the term received an academic acknowledgement. And today, there are numerous journals dedicated to scientometrics and its related fields like, Research Policy, Journal of Informetrics, Social Studies of Science, Journal of the American Society for Information Science and Technology, etc.

SCIENTOMETRIC INDICATORS

Bibliometric indicators aka Scientometric indicators (when referred in the field of Science) provide mathematical measures that are envisioned to quantitatively define the worth of scientific research and the scholarly publication in a particular domain. Scientometrics indicators are valuable assets for determining the capacity in terms of quality and quantity of scientific research of researchers, establishments or nations. El-Maamiry and Gauri (2013) define bibliometric indicator as a maneuver founded on bibliographic facts and figures employed to quantify and evaluate scientific scholarly output of an individual, institution, nation and so on. According to Vinkler (2001) Scientometric indicator is a scientometric measure which is accredited to scientometric organizations. To illustrate he has put forth the examples like Garfield Factor for a journal in a given year; Publication Productivity of an institution. Durieux and Gevenois (2010) emphasize that scientometric indicators are specifically essential for investigators and research institutions as these dimensions are frequently used in research funding, activities, and performance of researchers. They further elaborate that with increasing advances in scientific developments novel research is continuously asserted by new researchers thus making bibliometric indicators more significant. Scientometrics does not exist without the practice of quantitative information and indicators. According to him indicators are the spirit of scientometrics as they illustrate the communication process in science. Scientometric indicators are key parameters for the purpose of assessment and evaluation of scientific research output as they allow us to understand the prospective competitive aptitude of scientific research output and provide arithmetic measures to quantitatively define the worth of scholarly and scientific research, the impact and degree of scientific works

-as an auxiliary for the total scientific research output, as being reliable measures for evaluating and assessing the scientific research output and most importantly policy-making.

TYPES OF SCIENTOMETRIC INDICATORS

El-Maamiry and Gauri (2013) in their study have given three categories of bibliometric indicators. *Quantity indicators*, *Quality indicators* and *Structural Indicators*. *Quantity indicators* measure the total production of a researcher. *Quality indicators* measure the prominence and performance of researchers and *Structural indicators* signify the correlation between publications, researchers and research fields. A similar categorization of scientometric indicators has also been given by Durieux and Gevenois (2010). According to them, there are three types of bibliometric indicators: *Quantity indicators* measure the productivity of a particular researcher or research group. *Performance indicators* measure the quality of a journal, researcher, or research group. *Structural indicators* measure connections between publications, authors, or research fields. In this chapter, the scientometric indicators will be discussed under three classes, Quantity indicators, Quality indicators and Structural indicators. As per Durieux and Gevenois (2010) there are three types of bibliometric indicators: *Quantity indicators* measure the productivity of a particular researcher or research group. *Performance indicators* measure the quality of a journal, researcher, or research group. *Structural indicators* measure connections between publications, authors, or research fields.

PROMINENT SCIENTOMETRIC INDICATORS

Various scientometric indicators have been derived so far to measure the performance of research

production of institutions, researchers, research groups, journals and so on. Most of the indicators used to evaluate the scientific research eminence are citation based, which traditionally were derived from the Citation databases like SCI, SSCI, JCR etc. Later in 21st century, web-based databases like Web of Science, Scopus and citation search engines like Microsoft Academic Search, Google Scholar, CiteSeerX began to be used to derive indicators that can be used to evaluate research. These indices help in analyzing and assessing the quality, quantity and also the co-authorship networks, collaborations between researcher, groups, institutes or countries. Some of the prominent scientometric indicators that have been evolved so far are discussed here:

1. Hirsch-Index

Hirsch-index or h-index was proposed by a Physicist J.E. Hirsch in 2005. According to him a researcher has index h if h of his/her N_p papers have at least h citations each and the other papers have no more than h citations each (Hirsch, 2005). H-index is considered to be the appraisal of the influence of a researchers' aggregate research contribution. Today it is highly applied to enumerate the prominence, rank, worth, and comprehensive impression of researchers, research groups or research institutions. Some of the advantages of h-index have been put forth by Hirsch (2005) himself. The advantages pointed out are:

- It pools a measure of quantity in terms of publications and quality by indicating citations received by a research.
- It permits us to illustrate the research production of a scientist with objectivity helping in decision making regarding upgrades, scholarships and awards.
- It is better executed than various other indicators used to evaluate research output like impact factor, citation per paper, number of papers, etc.

- It is easy to understand and can be accessed simply via Thomson ISI Web of Science, Google Scholar.

Though h-index has received a great accolade in terms of research evaluation worldwide but it has come under the scanner for its various critical points. Bornmann and Marx (2003), BAR-ILAN (2008), Bornmann, Mutz, and Daniel (2008), Ball (2012), and Schreiber (2013) give following disadvantages of h-index:

- More citations in h-core is of no value.
- H-index is field-dependent like most of the pure citation measures.
- Self-citations can easily influence the calculations of h-index.
- There is a delinquency in finding of reference standards.
- Data collection for h-index calculation is quite hectic. A complete list of publications with their citations of a researcher is required for its calculation.
- A meticulous problem of h-index is that a complete name of a researcher is required to distinguish between researchers with same name.
- More specifically the index handicaps newcomers as their publications and citation rates are very low.
- It sanctions researchers to respite on their glories as citations increase over-time even if no new publication is added.

Due to a number of limitations of h-index, a number of variants of h-index like g-index, a-index, hg-index, m-index and so on have been introduced to overcome its deficiencies.

2. Impact Factor

Citations are an important factor in depicting the quality of scientific literature. The impact factor is based upon the count of these citations to determine the value of research. According to Saha,

Saint and Christakis (2003) Impact factor is the citations received by a journal article in scientific literature. It is given by the number of citations in year $n+1$ to a published work in a journal in year n divided by the total number of articles published in year n in that journal. This index as a journal quality index is based on the conception of citation frequency.

Many advantages of Impact factor have been put forth by experts. It is considered to be quite beneficial for knowledge administrators and researchers; information professionals and also the librarians. Some of the advantages of Impact factor given by Honekopp and Kleber, 2008, Khan and Hedge (2009), Garfield and Pudovkin (2015) are:

- It enables experts to draw a comparative relation between different journals and research groups.
- It's easily available to use and understand.
- Since Impact factor is fundamentally based on the citation patterns in a subject area it is considered to be an objective measure of quality of research thus having a wider acceptance worldwide.
- Impact factors reveal the actual status of a journal within a research field, as the number of citations increases or declines in a particular timespan.
- Impact factor is specifically used for the prediction of the forthcoming citations of an article. Further than this, there certainly are some intrinsic snags in journal Impact factor (IF). The disadvantages have been discussed below.

Disadvantages

Researchers Honekopp and Kleber (2008), Khan and Hedge (2009), Nisonger (2004), and Seglen (1997) have stated various problems that are associated with IF. Some of them are:

- Impact factor does not relate with definite citations of specific articles and hence can-

not be considered to be statistically representing individual journal articles.

- Inclusion of self-citations creates a mess.
- Citations to “noncitable” stuff are speciously encompassed.
- High citations to review articles leads to inflation of the impact factor of journals.
- Length of articles matters a lot. Lengthy articles receive more than short length papers.
- Citations within the same journals inflates IF.
- Books are not included as a source of citation in various databases which drops the IF.
- IF varies from year to year as citation number keeps changing.
- Prejudiced towards English language, hence leading American publications.
- IF depends upon expansion of research area and also the relations between various research fields.

3. G-Index

G-index is considered to be a well-known index to calculate the scientific output at a broader level (Woeginger, 2008). It was given by Leo Egghe in 2006 as the improved variant of h-index which defines the performance in terms of citations of an article at the global level. Egghe (2006) defines it as the f number of papers which receive total or more than g^2 citations. He further elaborates that $g \geq h$ and also the g-score is high when citations are high in the g-core.

Advantages

- G-index provides information regarding both the size and the impact of the g-core.
- More comprehensive than h-index.
- Rather than using many indexes like h-index, r-index separately for measuring output and eminence of research, combined g-index can be employed (Schreiber, 2009).

Disadvantages

Schreiber (2008, 2009, 2010) proposes various cons of g-index. According to him, following points should be reconsidered to improve the efficacy of g-index.

- Self-citations are ignored and excluded.
- The publication count are fractionalized.
- The collaboration index or the number of co-authors should be considered while calculating g-index.

4. M-Quotient

The m-quotient proposes to measure the academic term and length of a researcher despite his period of scientific career. It is given by:

$$h\text{-index}/k$$

where k designates the number of years since a researcher's first publication.

Advantages

- Career length is an important factor in calculation of m-quotient.
- Based on citation metrics.

Disadvantages

- The m-quotient of an author is not properly established till initial years of his/her career.
- Minor changes in h-index of an author can alter the m-quotient altogether.
- As it is based on h-index, it nevertheless furnishes it anomalies in terms of quality and quantity measurement.

5. Shanghai Ranking

Shanghai Ranking or Academic Ranking of World Universities (ARWU) is a yearly publication of

university rankings by Shanghai Ranking Consultancy. It is based on four criteria namely quality of education, quality of faculty, research output and Per Capita Performance. Quality of faculty represents highly cited researchers, Nobel Laureates and Field Medalists. The research output is measured on the basis of indicators like papers in NATURE and SCIENCE and also papers indexed by SCI (Zhang et al., 2015).

Advantages

- Its widely accepted Institutional Ranking System because of its transparency, methodology used and purpose.
- It is based on Scientific indicators like citations, research output, etc.

Disadvantages

- It is dependent on award factors decreasing the importance of instruction and humanities.
- It is widely criticized for the criteria it uses for ranking universities (Van Raan, 2005).
- Florian (2007) consider that any kind of ranking and numbering universities cannot be accurate in any kind of ranking system.

CONCLUSION

The evaluation of qualitative research is being prioritized throughout the world for grading of universities and research institutions which in turn affects the research funding of such institutions by different funding agencies. Therefore analyzing research in different areas has always been an uphill task for evaluating bodies that resulted in the development of different evaluation indicators for analyzing the qualitative research. The scientometric indicators particularly are of great use in the measurement and evaluation of the scientific research output but at the same time it

requires careful efforts in use. Despite criticism at various levels, most professionals believe in it and is one of the widely used indicator categories. Though there is abundant literature emphasizing critics' limits and partialities but academicians and researchers have confidence in it consider it the eminent method and agree that it is the only way to assess and evaluate the scientific research.

FUTURE RESEARCH DIRECTIONS

The arena of research in scientometric evaluation is evolving with the development of more specific variants of scientometric indicators. These indicators are widely being employed in evaluation of different parameters of research including the impact of Journal publications, articles and author performance. The field is continuously evolving with the incorporation of nascent indicators each day. However there is a dearth of most comprehensible indicators that can be employed to evaluate and analyse each aspect of the scientific productivity. Therefore further research needs to be carried out to study different dimensions associated with Scientometric indicators so as to be more precise and appropriate in revealing qualitative aspects of research.

KEY TERMS AND DEFINITIONS

R

H-Index: H-index is considered to be the appraisal of the influence of a researchers' aggregate research contribution.

Impact Factor: Impact factor is the citations received by a journal article in scientific literature.

Performance Indicators: These measure the quality of a journal, researcher, or research group.

Scientometric Indicators: Metrics founded on bibliographic facts and figures employed to quantify and evaluate scientific scholarly output of an individual, institution, nation and so on.

Scientometrics: The field within bibliometrics that quantifies and encompasses evaluation and assessment of scholarly content within the field of science.

Electronic Theses and Dissertations (ETDs)

Ralph Hartsock

University of North Texas, USA

Daniel G. Alemneh

University of North Texas, USA

INTRODUCTION

Academic libraries around the world are seeking to take advantage of the powerful forces that transform higher education, including new and rapidly changing technologies, an abundance of digital (mostly open access) resources in a myriad of formats, and changing practices in how scholars communicate and disseminate their research and creative work.

Theses and dissertations, the monograph-length essays required for graduate degrees from institutions of higher education, have evolved with the technology. Electronic Theses and Dissertations (ETDs) constitute the primary contributions to a community of research (Ramirez et al., 2014). The term “Electronic Theses and Dissertations” (ETD) is used primarily to differentiate between analog theses and dissertations (paper, microfilm) and their digital counterparts (digital objects). Since 1998, academic institutions increasingly publish theses and dissertations that are born digital.

BACKGROUND

As forms of scholarship evolve, so do users’ and creators’ expectations. Theses and dissertations represent part of the historical record of graduate education at the institution. Those produced prior to the advent of the photocopier were created by the use of carbon paper. However, often in the domain of music, the need for accompanying material required the student to attach a separate

sheet with the musical notation to each copy. Students attached photographs and illustrations, predominantly black and white, in much the same manner.

The first electronic theses and dissertations (ETD) project was launched in 1987 by a business company and a long-term vendor of theses and dissertations for academic libraries, University Microfilms International (UMI), by converting its large collection of dissertations on microfiches and microfilms going back to 1939 into electronic form. The first non-profit ETD hosted by a university was launched ten years later, in 1997, at Virginia Tech, which made electronic submission of theses and dissertations through its ETD system a requirement for the university’s graduating students (Ramirez et al., 2014). Virginia Tech University, along with representatives from UMI and the American Council of Graduate Schools, was one of the founders of the Coalition for Networked Information’s joint project, with the goal to collaboratively develop collections of ETDs. In 1995 this resulted in creation of the Networked Digital Library of Theses and Dissertations (Fox et al., 1997).

Since the late 1990s, an increasing number of academic institutions have mandated the electronic submission of theses and dissertations. Today, textual dissertations need only be in a word processing file and converted to a more permanent and unchangeable file format to become Electronic Theses and Dissertations (ETDs). The current digital submissions of ETDs experienced significant increased usage of graphics or multimedia contents.

DOI: 10.4018/978-1-5225-2255-3.ch584

During the analog age examples of handwritten music had to be glued into the dissertation, with the typescript below it; this included attaching the original music on the carbon copies. With the introduction of musical software (Finale, Sibelius) or imaging software, writers could place these materials inline inside the dissertation. A move to an all-digital means of providing electronic theses and dissertations is accelerating their discovery and facilitating their use, value, and impact in research.

Accompanying Materials

Rebecca Lubas (2009) and Cedar C. Middleton, Jason W. Dean, and Mary A. Gilbertson (2015) present adequate processes for the cataloging and metadata creation of homogenous textual dissertations. However, dissertations increasingly have accompanying materials, most prevalent in music and the performing arts: these have included audio tapes, compact discs, or video recordings of recitals, concerts, and lectures. Traditionally, these audio tapes, either in reel-to-reel or audio cassette format, or videocassettes, in various configurations, were difficult to preserve. Equipment also went out of date, as certain formats became dominant. Beta and U-Matic declined into more limited use as VHS became the standard for videocassettes. Discs, either CDs or DVDs, became the norm during the 1990s.

Since the introduction of ETDs, illustrations have become predominantly color, particularly in the arts and sciences. In addition to increased usage of graphics, those in biological and chemical fields include video demonstrations of their experiments, or may draw the elements and the design of molecules. Today, these are all submitted as streaming audio files or audio visual files and integrated seamlessly with the original ETDs.

Copyright Issues

While increased availability of interoperable Open Access content helps to integrate and enhance ac-

cess to diverse digital resources, they also bring about great challenges for traditional policies. There have been some concerns, questions, and misconceptions about various issues, ranging from intellectual property to quality issues. Two of the primary concerns about ETDs and their accompanying materials are copyright and fair use. Musical and artistic works created after 1923 are held in the creator's copyright until 75 years after that creator's death, due to the Berne Convention Implementation Act of 1988. Musical scores may be either brief examples that support the author's thesis, or comprise the primary contents of the thesis, as is done in new editions of music. Additionally, this affects open access to performances (audio or video) of these compositions, as it affects public performance rights (Dogan, 2011). Due to this, many institutions limit access to these recordings to those enrolled in classes or patrons on the campus. Open access has also been a concern for emerging authors wishing to publish their research in peer reviewed publications. Although some scholars consider this issue to be contentious, Ramirez et al. (2014) has alleviated this concern, stating that the thesis as a non-peer reviewed paper does not constitute double publishing.

Access and Cataloging

As forms of digital scholarship evolve, so do users' and creators' roles and expectations. The Open Access (OA) movement has become increasingly important in shaping the ways that academic libraries provide services to support the creation, organization, management, and use of digital contents. Making ETDs Open or the removals of barriers (pricing, technical and legal hurdles) facilitates successful management of ETDs across the entire life-cycle to ensure their preservation and continuous availability in a manner that current and future users expect. Even though some ETDs are restricted to their specific institutions' users, consulting the metadata description may convey sufficient information, and can be adequate for

most external users' needs. Making the metadata accessible to providers of search and discovery services via Open Archive Initiative Protocol for Metadata Harvesting (OAI-PMH) facilitates usability.

Successful retrieval of materials that are useful to a user relies on the quality of the information representation. In an ideal world, digital content would also be given the same consideration as other library materials, when conducting collection development, organization and cataloging of works, etc.

In information science, an ontology is a formal naming and definition of the types, properties, and interrelationships of the entities that fundamentally exist for a particular domain of discourse. It is thus a practical application of philosophical ontology, with a taxonomy. Historically, ontologies arise out of the branch of philosophy known as metaphysics, which deals with the nature of reality – of what exists. An ontology compartmentalizes the variables needed for some set of computations and establishes the relationships between them (Pawletta et al., 2014). This necessity of relationships is accentuated in music, due to the relationships between the composer, the work, and those who perform recordings of these works. Ludwig van Beethoven composed nine symphonies, each published by different organizations, and recorded by numerous conductors, from Arturo Toscanini to Leonard Bernstein.

The generation of accurate indexing terms is critical to the discovery and use of specific manifestations. However, in practice it is difficult to comprehensively represent every item with appropriate descriptions and index terms. According to Alemneh and Hartsock (2014a), because ETDs usually constitute original research, each is unique to the bibliographic world; as a result, catalogers need to provide original cataloging (i.e., creation of metadata record from scratch) as opposed to copy cataloging (i.e., use of pre-existing metadata records with or without augmentations) to describe each ETD. When catalogers employ traditional controlled vocabularies, such as the Library of

Congress Subject Headings (LCSH), creating access to these original theoretical researches becomes challenging and labor intensive. (Lubas, 2009) Considering the multi-disciplinary and interdisciplinary characteristics, several subjects and terms need to be supplied frequently to adequately represent ETDs for efficient access. Middleton et al. (2015) notes that it is uncommon to provide full level cataloging to theses and dissertations because of this increased labor. But a research status of a certain number of institutions affects accessibility and expectations of graduate students. Thus, these metadata specialists may provide full level cataloging in MARC (Machine-Readable Cataloging) and more universal descriptive standards like RDA (Resource Description and Access) to their dissertations. MARC was developed during the 1960s at the Library of Congress as a model for data input and retrieval (Seikel et al., 2011). It employed three character numerical codes, which utilized 8 bit memory as opposed to natural language labels. A majority of library catalogs online use MARC data, with public viewable interfaces installed by local system vendors. This translates the numerical code into readable labels. The new RDA standard provides a comprehensive set of guidelines and instructions for the creation of descriptions and access, covering all types of digital contents and media. (American Library Association, 2010).

Furthermore, in some disciplines, the subject can also be an aspect of study. Recently introduced are genres and forms, through seven projects of the Library of Congress Genre/Form Terms (lcgft). Several professional associations provided guidance in the formulation of these terms. Beginning in 2007, the Policy and Standards Division (PSD) of the Library of Congress formulated thesauri of genre/form terms for moving images, cartography, law, literature, religion, music, and non-musical sound recordings (predominantly radio programs) (Young et al., 2013) Many genres and forms are combined into a single term. Genre indicates a category of works that is characterized by a similar plot, theme, setting, situation, or characters (such

as Horror, Thriller, Western, Country). Form denotes a category of works with a particular format and/or purpose (for example, Film, Sonata, Symphony, Opera, etc.). Catalogers may add another Genre/Form for textual dissertations, the lcgt of “Academic theses.” A dissertation author may produce an edition of music, or create an original composition; the cataloger then adds the genre of the music in the ETD, for example, Anthems, Madrigals, Folk songs, or Symphonies.

Within the context of radio, genre/form terms denote categories of programs. They describe a program according to its content (Westerns, Biographies), style (Audience Participation Programs, Call-in Shows), topic (Crime or Mystery Programs), structure (Magazines, Anthologies), intended audience (Children’s Programs), method of transmission (Shortwave Broadcasts) or combinations of these. A genre/form category suggests a common theme, motif, setting, situation or characterization that is easily recognizable.

That means, in addition to denoting “Aboutness,” certain music and other subjects will have “Isness” as well, referred to as content in RDA (McKnight, 2012). To illustrate this, current practice prescribes that Sonata, Symphony, or Opera represent a subject in the LCSH when singular, indicating resources that discuss the form itself. For a genre/form term, the plural indicates that this is a manifestation of the genre: a score or a recorded performance.

In music, the author achieves originality by analyzing a specific composer or composition(s), or applying a unique approach or analysis to a specific composition. This aspect may be applied to several works by various composers. For example, multiple dissertation writers may analyze extended techniques that employ specific instruments (trumpet, vibraphone) in relation to specific compositions (Meredith, 2008; Smith, 2008).

During the analog age, from the invention of the printing press until the 1980s, the carrier determined the content of its material. Thus, books are textual and printed, audiocassettes are sound recordings on tape 1/8 inch wide, while VHS is

the standard for 1/2 inch wide videocassettes. The digital age has not only made texts and images interactive, but releases content types from single carriers. Today, a DVD may be audio or video, contain moving images, or still images, sound, textual files, and even games.

In certain disciplines, institutions require the student to perform a recital (vocal or instrumental), and to present a lecture about a specific aspect of a composition, to be performed at the Lecture-Recital. The dissertation is a textual representation of this lecture. To provide access to all facets of ETDs, metadata departments must integrate the cataloging of all the formats involved, not just the text.

In the transitory period between the late analog and the early digital age, recitals were submitted on audiocassettes, or if visual, on videocassettes. These videos could be in a number of formats, but VHS predominated. Later, students submitted their audio recordings on compact discs. The digital reformation makes possible the submission of these aural and visual data via streaming mechanisms. The electronic manifestation of the ETD becomes the record of choice, and the cataloger may provide full level access, including description, subjects from a controlled vocabulary, classification numbers, and functioning links, not only for the textual dissertation (Middleton et al., 2015), but to all accompanying materials via multiple linking fields, such as the MARC (Machine-Readable Cataloging) 856.

While the subjectivity and objectivity of the process and the need to distinguish functional representation from mere descriptions of a topic still exist, recording these data has evolved from the earlier cataloging methods using *Anglo-American Cataloging Rules* (AACR), and *Anglo-American Cataloging Rules, 2nd edition* (AACR2), to the current practice of *Resource Description and Access* (RDA). Catalogers provide Library of Congress Subject Headings (LCSH) for the topics of each dissertation. In addition, those of musical editions contain a Medium of Performance field, located in the MARC format as the 382 tag. This

presents a granular statement of the personnel necessary for an execution of the work, and uses a controlled vocabulary developed by the Library of Congress, with assistance from the Music Library Association. For Gregory Alan Schneider's *I never saw Another Butterfly: A Composition for SATB Choir and Chamber Orchestra* (Schneider, 1997), the LCSH may be represented by a MARC 650 tag: Choruses, Secular (Mixed voices) with chamber orchestra. The Library of Congress Medium of Performance Thesaurus statement (LCMPT) more granularly exhibits which voices are represented in this chorus.

This would display to the cataloger in MARC as:

382 01 mixed chorus \$v SATB \$a orchestra \$2 lcmpt

The public would see this as:

Performance medium: mixed chorus (SATB), orchestra.

FUTURE RESEARCH DIRECTIONS

Theses and dissertations represent a wealth of scholarly and artistic content created by graduate students in masters and doctoral programs in the degree-seeking process. The digital environment has now introduced new resource types into the current information landscape, accompanied by new user expectations. Advancing knowledge requires not only enhancing our capacity to generate more knowledge, but also cultivating our ability to provide seamless discovery processes to the vast quantities of knowledge we continue to generate. As the starting points for new researches are increasingly digital, catalogers and metadata specialists need to provide adequate descriptions of digital contents sufficient to ensure successful information retrieval.

Arguably, ETDs have experienced a continuous evolution in format and structure that require dif-

ferent lifecycle management practices to facilitate access, use, and reuse. Accompanying materials in the ETD landscape can be diverse, ranging from simple visual forms of maps or diagrams to complex and high resolution images of art objects or videos of lab observations. As demonstrated by Alemneh et al. (2014), by employing appropriate metadata elements that link various characteristics and relationships, ETDs' associated contents can be integrated. In light of such diverse contents and formats, institutions integrate and contextualize all parts of ETDs to add value and enhance access and use.

Poole (2015) argued that harnessing the principles and practices of digital curation (ranging from managing quality metadata, provenance and authenticity to ensuring long-term access and trust) facilitate the sharing, access, and reuse of scientific data. Doing so also allows researchers and other stakeholders to address new imperatives in scholarly research.

CONCLUSION

There has been a shift in the way users search, access, and use ETDs. In principle, cataloging or metadata descriptions still serve the same function that they always have: to link creators with users. In other words, by describing information resources adequately, whenever users express their information need, using the best possible descriptor or search term, the results obtained match their information needs. However, in the increasingly self-structured Web 2.0 environment, it is clear that traditional user experience and access methods of a simple ranked list of search results will be of limited utility. Various emerging Web applications – driven by semantic web technologies such as the resource description framework (RDF), semantic Web rules language (SWRL), and other members of the World Wide Web Consortium (W3C) family of specifications – offer powerful data organization, combination, and query capabilities. All these have serious im-

plications for how ETDs are curated. Consequently catalogers have changed their methodology and procedures significantly over the past few decades. Deployment of new cataloging standards including RDA and the exposure of RDA-based data in the linked data cloud have already transformed the traditional practices. Effective metadata descriptions, taxonomies, and ontologies add value and amplify the mostly interdisciplinary ETDs. Complex retrieval systems allow visualization of the information space, among other things—allowing ETD users to explore and delve deeper in multi-dimensional ways.

KEY TERMS AND DEFINITIONS

Catalog: Textual representation of bibliographic information for materials, either in analog (i.e., card catalog) or digital (i.e., online catalog) forms; online catalogs employ natural language labels, each derived from MARC (Machine Readable Cataloging) numerical data.

Digital Curation: The active management, preservation, and enrichment of digital resources.

ETD: The term “Electronic Theses and Dissertations” (ETD) is used primarily to differentiate between analog theses and dissertations (paper, microfilm) and their digital counterparts (digital objects). However, “ETDs” may also be digitized or born digital.

Intellectual Property Rights: Refers to creations of the mind: inventions; literary and artistic works and symbols, names, images, and designs used in commerce.

LCGFT: Library of Congress Genre Form Thesaurus (LCGFT) is a controlled vocabulary of genres and forms maintained by the United States Library of Congress, for use in bibliographic and authority records.

LCMPT: Library of Congress Medium of Performance Thesaurus (LCMPT) is a controlled vocabulary maintained by the United States Library of Congress, for use in bibliographic

and authority records. Terms provide maximum granularity of the medium of performance.

LCSH: Library of Congress Subject Headings (LCSH) is a controlled vocabulary maintained by the United States Library of Congress, for use in bibliographic records.

MARC: Machine-Readable Cataloging (MARC), a data retrieval system developed during the 1960s at the Library of Congress. It employed three character numerical codes, which utilized 8 bit memory as opposed to natural language labels.

OA: Open Access (OA) refers to online research outputs freely accessible, without restrictions on costs (e.g. access tolls) or use (e.g., copyright, performance rights, and licensing).

OAI-PMH: Open Archives Initiative Protocol for Metadata Harvesting (OAI-PMH) is a mechanism developed for harvesting metadata descriptions of records in an archive.

RDA: Resource Description and Access (RDA) is a standard for descriptive cataloging initially released in 2010, providing instructions and guidelines on formulating bibliographic data. RDA divides bibliographic entities into works, expressions, manifestations, and items.

RDF: Resource Description Framework (RDF) is a standard model for data interchange on the Web, facilitates data merging across several schemas.

The Nature of Research Methodologies

Ben Tran

Alliant International University, USA

INTRODUCTION

In the research community, according to Tran (2015), the process of research, is generally defined as the procedures used in research that involve introducing a problem, narrowing the research problem into purpose statements, research questions, and hypotheses, collecting and analyzing data to address these questions and hypotheses, and using a writing structure that best fits the problem and the methods. Hence, terms such as *investigator* (often associated with quantitative research) and *inquirer* (often associated with qualitative research) are used interchangeably. Thus, a *methodology* refers to the philosophical framework and the fundamental assumptions of research (van Manen, 1990), *research design* refers to the plan of action that links the philosophical assumptions to specific methods (Creswell, 2003; Crotty, 1998), and *methods* are techniques of data collection and analysis (Creswell, 2003; van Manen, 1990). Some mixed methods writers, like Tashakkori and Teddlie (1998), consider this form of research a methodology and focus on the philosophical assumptions. To call a process a *methodology* introduces a complexity to the process of research. Other mixed methods writers, like Creswell, Plano-Clark, Guttman, and Hanson (2003), Greene, Caraceli, and Graham (1989), and Onwuegbuzie and Teddlie (2003), emphasize the techniques or methods of collecting and analyzing data. To call mixed methods research a *method* is clean and concise and resonates with many researchers (Elliott, 2005). The purpose of this chapter is to cover the three types (trends) of research methodologies: the traditional (quantitative, qualitative), the universal (mixed-methods),

and the trends (blogs, webinars, virtual intercepts, and virtual reality). This chapter will also cover a brief history of research methods and the usage of research methodologies.

BRIEF HISTORY OF RESEARCH METHODOLOGIES

Before the advent of mixed methods, many studies used multiple methods to achieve the benefits of triangulation (Galton & Wilcocks, 1983) without restricting themselves to any paradigmatic membership or methodological category (Tashakkori & Teddlie, 2003). Thus, during the last 50 years, writers have used different names, making it difficult to locate articles that might relate to mixed methods research. Mixed methods has been called *multitrait/multimethod research* (Campbell & Fiske, 1959), *integrated* or *combined* (Johnson & Onwuegbuzie, 2004, p. 17; Steckler, McLeRoy, Goodman, Bird, & McCormick, 1992), and *quantitative and qualitative methods* (Fielding & Fielding, 1986). It has been called *hybrids* (Ragin, Nagel, & White, 2004), *methodological triangulation* (Morse, 1991a), *combined research* (Creswell, 1994), and *mixed methodology* (Tashakkori & Teddlie, 1998). It has also been called the *third methodological movement* (Tashakkori & Teddlie, 2002, p. 5), the *third research paradigm* (Johnson & Onwuegbuzie, 2004, p. 15), and *a new star in social science sky* (Mayring, 2007, p. 1). Nevertheless, the beginning of mixed methods is cited by some (Creswell & Plano-Clark, 2007, p. 5; Johnson, Onwuegbuzie, & Turner, 2007) to Campbell and Fiske (1959) as *multitrait* of *multimethod* research, a concept later formalized by

Webb, Campbell, Schwartz, and Sechrest (1966) as *triangulation* (Greene, Caracelli, & Graham, 1989), and is often cited as having methodological superiority over single methods (Johnson et al., 2007; Tran, 2014a). For the first 60 years or so of the 20th century, mixed research can be seen in the work of cultural anthropologists and, especially, the fieldwork sociologists (Gans, 1963; Hollingshead, 1949; Jahoda, Lazarsfeld, & Zeisel, 1931/2003; Lynd & Lynd, 1929/1959).

In social science methodological literature, Campbell and Fiske's (1959) article introduced the idea of triangulation, referring to *multiple operationalism* (Bouchard, 1976). Today, the most frequently used name is *mixed methods research*, a name associated with the *Handbook of Mixed Methods in Social and Behavioral Research* (Tashakkori & Teddlie, 2003). Furthermore, early researchers' idea of multiple operationalism follows more closely what today is called *multimethod research*, in contrast to what currently is called *mixed methods research*. However, Campbell and Fisk (1959) are rightfully credited as being the first to show explicitly how to use multiple research methods for validation purposes, and were extended further by Webb, Campbell, Schwartz, and Sechrest (1966). Thus, Webb et al. are credited with being the first to coin the term *triangulation*. With that said, Cook (1985) is credited for coining the term critical multiplism (also see Houts, Cook, & Shadish, 1986).

THE USAGE OF RESEARCH METHODOLOGIES

In the usage of research methodologies, it was Denzin (1978, p. 291) who first outlined how to triangulate methods. Denzin outlined the following four types of triangulation: (1) data triangulation, (2) investigator triangulation, (3) theory triangulation, and (4) methodological triangulation (Tran, 2014a). According to Tran (2014a), Denzin also distinguished *within-methods* triangulation, from

between-methods triangulation (Tran, 2014a). According to Denzin, three outcomes arise from triangulation: convergence, inconsistency, and contradiction. Furthermore, Jick (1979) noted the following advantages of triangulation: (1) it allows researchers to be more confident of their results, (2) it stimulates the development of creative ways of collecting data, (3) it can lead to thicker, richer data, (4) it can lead to the synthesis or integration of theories, (5) it can uncover contradictions, and (6) by virtue of its comprehensiveness, it may serve as the litmus test for competing theories (Tran, 2014a). Morse (1991b) on the other hand, outlined two types of methodological triangulation: simultaneous or sequential.

Sieber (1973) provided a list of reasons to combine quantitative and qualitative research data that can play a role in providing baseline information and helping to avoid *elite bias*. Rossman and Wilson (1985) identified three reasons for combining quantitative and qualitative research: (1) used to enable confirmation or corroboration of each other through triangulation, (2) used to enable or develop analysis in order to provide richer data, and (3) used to initiate new modes of thinking by attending to paradoxes that emerge from the two data sources. By examining published research, Greene, Caracelli, and Graham (1989) inductively identified the following five broad purposes of rationales of mixed methodological studies: (1) triangulation, (2) complementarity, (3) development, (4) initiation, and (5) expansion. Sechrest and Sidana (1995) listed four reasons for methodological pluralism: (1) for verification purposes, (2) to provide some basis for estimating possible error in the underlying measures, (3) to facilitate the monitoring of data collected, and (4) to probe a data set to determine its meaning. Also, Dzurec and Abraham (1993) identified the following six *pursuits* that link qualitative and quantitative research: (1) the pursuit of mastery over self and the world, (2) the pursuit of understanding through recomposition, (3) the pursuit of complexity reduction to enhance understanding,

(4) the pursuit of innovation, (5) the pursuit of meaningfulness, and (6) the pursuit of truthfulness (pp. 76-77).

Furthermore, Collins, Onwuegbuzie, and Sutton (2006) identified four rationales for conducting mixed research: participant enrichment, instrument fidelity, treatment integrity, and significance enhancement. In sum, the 20th century, according to Tran (2015), started with some use of what later came to be called mixed research, but social and psychological research quickly became primarily quantitative and coalescing into a qualitative research paradigm in the 1980s and 1990s (Guba, 1990). In reaction to the polarization between quantitative and qualitative research, another intellectual movement occurred, and it has come to be called mixed methods research, all thriving and coexisting. In contrast to Thomas Kuhn's (1962) expectation for single paradigms characterizing *normal science*, the research community suggest that a three-paradigm *methodological* world might be healthy because each approach has its strengths and weaknesses and times and places of need.

Research Methodologies: Traditional (Quantitative and Qualitative)

Quantitative research options have been predetermined and a large number of respondents are involved. By definition, measurement must be objective, quantitative and statistically valid. Simply put, it is about numbers, and objective hard data. The sample size for a survey is calculated by statisticians using formulas to determine how large a sample size will be needed from a given population in order to achieve findings with an acceptable degree of accuracy. Generally, researchers seek sample sizes which yield findings with at least a 95% confidence interval, plus/minus a margin error of 5% points. Hence, quantitative data are divided into two main categories, descriptive and continuous (Tran, 2014a, 2015).

According to Tran (2014a, 2015), qualitative research is collecting, analyzing, and interpreting data by observing what people do and say. Where-

as, quantitative research refers to counts and measures of things, qualitative research refers to the meanings, concepts, definitions, characteristics, metaphors, symbols, and descriptions of things. Qualitative research is much more subjective than quantitative research and uses very different methods of collecting information, mainly individual, in-depth interviews, and focus groups. The nature of this type of research is exploratory and open-ended. Qualitative data consists of open-ended information that the researcher gathers through interviews with participants. Hence, qualitative data are divided into two main categories, nominal and ordinal.

Research Methodologies: Universal (Mixed Methods)

Mixed methods research has been established as a third methodological movement over the past twenty years, complementing the existing traditions of quantitative and qualitative movements (Tashakkori & Teddlie, 2003; Teddlie & Tashakkori, 2009). The term *mixed methods* has come to be used to refer to the use of two or more methods in a research project yielding both qualitative and quantitative data (Creswell & Plano-Clark, 2007; Greene, 2007; Teddlie & Tashakkori, 2009). Multimethods do not have the same paradigmatic problem as do mixed methods since they can adopt the paradigm appropriate to the single type of data being collected. The paradigm problem for mixed methods arises because of the so called paradigm wars of the 1970s and 1980s where the positivist paradigm of quantitative research came under attack from social scientists supporting qualitative research and proposing constructivism, or variants thereof, as an alternative paradigm (Guba & Lincoln, 1994; Reichhardt & Rallis, 1994). To deal with this problem a range of alternative approaches have been developed (Creswell & Plano-Clark, 2007; Tashakkori & Teddlie, 2003). These approaches, according to Hall (2013), can be classified into three basic categories: a-paradigm stance, multiple paradigm

approach, and the single paradigm approach. The first of these simply ignores paradigmatic issues altogether, the second asserts that alternative paradigms are not incompatible and can be used in the one research project, and the third claims that both quantitative and qualitative research can be accommodated under a single paradigm. A paradigm may be viewed as a set of *basic beliefs* that deals with ultimate or first principles. It represents a *worldview* that defines, for its holder, the nature of the *world*, the individual's place in it, and the range of possible relationships to that world and its parts (Guba & Lincoln, 1994).

Mixed Methods Approaches

Research studies are becoming increasingly diverse and inclusive of both quantitative and qualitative methods—that is, they are mixing methods to address specific objectives (Tran, 2014a, 2015). The basic premise behind using a mixed methods research design is that *the combined* of both approaches provides a better understanding of a research problem than either approach could alone. Creswell and Plano-Clark (2011) argue that integrating methodological approaches strengthens the overall research design, as the strengths of one approach offset the weaknesses of the other, and can provide more comprehensive and convincing evidence than mono-method studies. Another more practical benefit is that mixed method research can encourage interdisciplinary collaboration and the use of multiple paradigms. There are more than a dozen mixed methods research typologies in the literature, each emphasizing different angles. For the most part, however, typologies include at the very least two basic dimensions—timing of data integration and purpose of integration (Guest et al., 2012). The two most commonly used terms in this regard are *sequential* and *concurrent* designs (Creswell & Plano-Clark, 2007; Morgan, 1998; Morse, 1991b).

Mixing the Data: Quantitative and Qualitative

R

The mixing of data is a unique aspect of the research community when it comes to definition. By mixing the datasets, the researcher provides a better understanding of the problem than if either dataset had been used alone. There are three ways in which mixing occurs: merging or converging the two datasets by actually bringing them together, connecting the two datasets by having one build on the other, or embedding one dataset within the other so that one type of data provides a supportive role for the other dataset. Thus, it is not enough to simply collect and analyze quantitative and qualitative data, they need to be *mixed* in some way so that together they form a more complete picture of the problem than they so when standing alone (Tran, 2015).

FUTURE RESEARCH DIRECTIONS: RESEARCH METHODOLOGIES: TRENDS (BLOGS, WEBINARS, VIRTUAL INTERCEPTS, AND VIRTUAL REALITY)

Design decisions depend on the purposes of the study, the nature of the problem, and the alternatives appropriate for its investigation. Once the purposes have been specified, the study should have explicit scope and direction, and attention can be focused on a delimited target area. Design alternatives can be organized into nine functional categories based on these problem characteristics (Isaac & Michael, 1995, pp. 45-47): historical, descriptive, developmental, case or field, correlational, causal-comparative, true experimental, quasi-experimental, and action. Traditional qualitative research methods, like study groups, polls and observational studies, are going digital and expanding the ability for researchers and busi-

nesses to target participants and collect information. The following are four types of qualitative trends: virtual intercepts, virtual reality (Bryson, N. Y.), blogs, and webinars.

- **Blogs:** A blog is a personal internal journal, a discussion, or an informational site published on the World Wide Web and consisting of discrete entries typically displayed in reverse chronological order.
- **Webinars:** Web conferencing may be used as an umbrella term for various types of online collaborative services including web seminars (or webinars), webcasts, and peer-level web meetings. It may also be used in a more narrow sense to refer only to the peer-level web meeting context, in an attempt to disambiguate it from the other types of collaborative sessions.
- **Virtual Intercepts:** A web intercept (survey) is a survey which is used by websites to get feedback from users and visitors about the website. Such surveys are used to collect information regarding the website and how helpful it is for the users. A web intercept survey is an easy and quick way to intercept a website's performance consisting of a few main questions which are related to the topics directly and are usually objective in nature. Researchers can intercept respondents online from social media or surveys and route them into a one-on-one interview.
- **Virtual Reality** A technology-based Tavistock Method (Tran, 2014b) for research that harnesses virtual and augmented reality to enhance the research experience—for participant and client alike. Virtual reality captures new data, creates new experiences, and gives new insight by creating amazing reproductions of the physical world. With virtual reality technology, “where” becomes “anywhere”. Researchers can bring more people together—in virtual environments—than ever be-

fore. Researchers can bring people together from all across the country, or the world, and capture fresh data and experience it all “through the eyes” of the participants.

CONCLUSION

According to Tran (2015), debates about singular or universal truths or approaches to viewing the world (Socrates, Plato), versus multiple or relative truths (the Sophists such as Protagoras and Gorgias), versus balances or mixtures of the extremes (Aristotle's “golden mean” or principle of balance, moderate skepticism, Cicero, Sextus Empiricus), go back, at least, to ancient Western philosophy, and the spirit of these debates lives today in the different views of the three major approaches to social research. This debate continues to affect how we view knowledge, what we look for, what we expect to find, and how we believe we are to go about finding and justifying *knowledge*. Mixed research is between the extremes Plato (quantitative research) and the Sophists (qualitative research), with mixed research attempting to achieve a workable middle solution for many (research) problems of interest. Hence, research paradigms address the philosophical dimensions of social sciences (Tran, 2015). A research paradigm is a set of fundamental assumptions and beliefs as to how the world is perceived which then serves as a thinking framework that guides the behavior of the researcher (Jonker & Pennink, 2010).

Some writers (e.g. Berry & Otley, 2004; Creswell, 2009; Neuman, 2011; Saunders, Lewis, & Thornhill, 2009) emphasizes that it is important to initially question the research paradigm to be applied in conducting research because it substantially influences how one undertake a social study from the way of framing and understanding social phenomena. According to Arbnor and Bjerke (2008), Guba (1990), Guba and Lincoln (1994), and Wahyuni (2012), the two main philosophical dimensions to distinguish existing research paradigms are ontology and epistemology (Kalof,

Dan, & Dietz, 2008; Laughlin, 1995; Saunders, Lewis, & Thornhill, 2009), whereas only Arbner and Bjerke (2008), Guba (1990), and Guba and Lincoln (1994) claim that is a *third paradigm*: methodology. As such, quantitative research and quantitative research data are static through time, compared to qualitative and qualitative data, but still have functional uses and are relevant in the digital world. According to Bryson (N. Y.), deliberative and participative research methods are gaining popularity due to their increased ability to discover information on a larger scale. For instance, the largest growth is found in social media and mobile market research, and such technologies ranges from high-definition video conferencing and instant communication around the world to the ability to reach participants on their mobile devices and access to demographics that are traditionally hard to reach, the Internet is providing technology based research methods like blogs, webinars, virtual intercepts, and virtual reality. According to Bryson (N. Y.), three of the five trends gaining traction in digital qualitative research are: (1) market research online communities, (2) social media and qualitative research, and (3) mobile ethnography.

KEY TERMS AND DEFINITIONS

Between-Methods Triangulation: Involves the use of both quantitative and qualitative approaches.

Mixed-Methods Research: Is an approach to knowledge that attempts to consider multiple viewpoints, perspectives, positions, and standpoints.

Mixing Data: There are three ways in which mixing occurs: merging or converging the two datasets, connecting the two datasets by having one build on the other, or embedding one dataset within the other.

Paradigm (Research): Is a common body of beliefs, assumptions, and rules that govern research.

Qualitative Data: Consists of open-ended information that the researcher gathers through interviews with participants.

Qualitative Research: Is much more subjective than quantitative research and uses very different methods of collecting information, mainly individual, in-depth interviews, and focus groups.

Quantitative Data: Quantitative data includes closed-ended information such as that found on attitude, behavior, or performance instruments.

Quantitative Research: Refers to the meanings, concepts, definitions, characteristics, metaphors, symbols, and descriptions of things.

Triangulation: Is the combination of methodologies in the study of the same phenomenon. The four types of triangulation: (1) data triangulation, (2) investigator triangulation, (3) theory triangulation, and (4) methodological triangulation.

Within-Methods Triangulation: Refers to the use of either multiple quantitative or multiple qualitative approaches.

Research Methodology

INTRODUCTION

Research is the process to find solution to a problem through the planned and systematic collection of data, analysis, verification and interpretation of data. Research is the very important process for accessing knowledge for promoting progress and to enable people to relate more effectively to his environment to accomplish his aim and to resolve his conflicts. The research is primarily carried out to discover new facts, to verify and test important facts, to analyze an event or process or phenomenon, to identify the cause and effect relationship, to develop new scientific tools and techniques, concepts and theories, to solve and understand scientific and nonscientific problems (Rajasekar, Philominathan and Chinnathambi, 2006). In daily life new problems, events, phenomena and processes occur every day. Practically, implementable solutions and suggestions are required for tackling new problems that arise. Scientists have to undertake research on them and find their causes, solutions, explanations and applications (Gogoi and Goowalla, 2015).

The term 'Research' consists of two words; Re and Search. 'Re' means again and again and 'Search' means to find out something (Pandey & Pandey, 2015).

According to Clifford Woody of the University of Michigan, "Research is a carefully inquiry or examination in seeking facts or principles; a diligent investigation to ascertain something."

According to C. Francies Rummel, "Research is an endeavour to discover, develop and verify knowledge. It is an intellectual process that has developed over hundreds of years, ever changing in purpose and form and always searching for truth" (Pandey & Pandey, 2015; Kothari, 2004; Singh, 2006).

BACKGROUND

In the 1600s the origin of modern scientific method occurred in Europe.

- **Copernicus:** A scientific model that could be verified and checked by observation.
- **Tycho Brahe:** Accurate instrumental observations to confirm the model.
- **Johannes Kepler:** Theoretical examination of experimental data.
- **Galileo Galilei:** Scientific laws developed from experiment.
- **Rene Descartes:** Mathematics to quantitatively show theoretical ideas.
- **Isaac Newton:** Theoretical derivation of an experimentally confirmable model.
- **Karl Popper:** Scientific theory should make predictions and can be tested and verified (Frederick, 2011; https://en.wikipedia.org/wiki/History_of_scientific_method).

OBJECTIVE OF RESEARCH

1. To gain knowledge with a phenomenon or to achieve new perceptions into it.
2. To draw accurately the characteristics of a particular situation, individual or a group.
3. To determine the time frame with which something occurs or with which it is associated with something else.
4. To test a theory of a causal relationship between variables that is to analyses process or phenomenon.
5. To discover new facts; verify and test important facts.
6. To develop new concepts, theories and scientific tools to solve and understand the problems.
7. To find answers to scientific, nonscientific and social problems and to overcome the problems occurring in everyday life (Gogoi and Goowalla, 2015; Bhawna, and Gobind 2015).
3. It requires expertise.
4. Research involves collecting new data or information from primary or first-hand sources or using existing information for a new motive.
5. It based upon observable experience or empirical proofs.
6. Research demands accurate systematic observation, description and accurate investigation.
7. It is characterized by carefully designed methods or plan that applies careful analysis.
8. It achieves to organize data in quantitative terms.
9. It generally requires inexpensive informational data.
10. It is based on mutually depends upon causes and effect.
11. It sometimes requires courage (Pandey and Pandey, 2015; Kumar, 2015).

CHARACTERISTICS OF RESEARCH

1. It is directed toward the solution of a problem.
2. It gives special importance to the development of generalizations, principles, or theories that will be helpful in predicting future events.

TYPES OF RESEARCH

The research is broadly classified into two main categories as Fundamental or Basic and Action or Applied. Various ways through which research may classify is summarizes in Figure 1 and Table 1.

Figure 1. Classification of research

Table 1. Classification of research

On the Basis	Types of Research	Explanations
Levels	Basic level	Basic level as basic research. It does not necessarily produce results of immediate practical value and is designed to add an organized framework of scientific knowledge.
	Applied level	Helps to solve an immediate practical problem and the goal of adding scientific knowledge is secondary.
Objectives of Research	Fundamental	These research are applicable to all cases.
	Action	Applicable for certain conditions so it's utility is limited.
Approach of Research	Longitudinal	Case study, historical research, genetic comes under this type of research.
	Cross sectional	Survey and experimental research are the examples of cross sectional research.
Precision in Research Findings	Experimental	Such research are precise.
	Non experimental	Non-experimental research is not precise.
Nature of Findings	Explanatory	Such researches explain more concerned laws, principles and theories.
	Descriptive	These research are more concerned with the facts.
National Science Foundation	Basic	Those researches which accept origin or unique inspection for the advancement of knowledge.
	Applied	It may be characterized as the usefulness in practice
	Development	It uses scientific knowledge for the production of useful devices, systems, methods, materials for processes excluding design and production engineering.
Another Classification	Adhoc	This research is the class of inquiry used for a purpose alone and special.
	Empirical	Depends upon the observation or experience of phenomena and incident.
	Explained	Explained research is based on a theory.
	Boarder line research	In boarder line research involves main two branches or areas of science. For example study of public school finance.

1. Basic Research

Investigation or research studies of some natural phenomenon or relating to pure science are called as basic research or theoretical research. It is a finding solution on basic principles and reasons for occurrence of a particular process or phenomenon. Such researches some time may not lead to immediate application or use; not concerned with finding solution of any practical problems of immediate interest.

Many applied research uses base that comes from outcomes of basic research. Research concerning some natural phenomenon or process or relating to pure mathematics, research studies deals with human behavior studied with a view to make generalizations about human behavior and elementary particles results in identification

of new particles are the examples of fundamental research.

Basic research is an attempt to find answers to the following questions.

- Why materials are look like that?
- How does sodium melt?
- Why is sound produced when liquid is heated? (Pandey and Pandey, 2015; Patil and Mankar, 2016; http://www.mech.hku.hk/bse/bbse3002/Research_Methodology.pdf).

2. Applied Research

An applied research involves solving certain problems or issues by employing well known and accepted theories and principles. Most of

the case studies, experimental study, and interdisciplinary research are mainly applied research. Aim of Applied research is finding a solution or conclusion for an immediate problem facing a society or organization.

For example, research having immediate potential applications such as increasing efficiency of a production machine, increasing gain factor of production of a material, pollution control and preparing vaccination for a disease etc. (Pandey and Pandey, 2015; Patil and Mankar, 2016; http://www.mech.hku.hk/bse/bbse3002/Research_Methodology.pdf).

3. Experimental Development

Experimental development is systematic approach, knowledge gained from research and empirical experience, which is directed to producing new products, services and devices; to installing new systems, procedures, processes, and services; or to improving significantly those already produced or installed.

For examples, study of a polymerization reactions of given class under various reaction conditions; includes experimental development as scaling up process which has been optimized at the laboratory level and investigating and evaluating possible reaction methods for producing the polymer (Fracati, 2002).

4. Quantitative and Qualitative Methods

The applied and basic researches can be quantitative or qualitative or even both.

- **Quantitative Research/Method:** Is mainly based on the quantification or measurement of quantity or amount. Quantitative research is numerical, non-descriptive and applies statistics or mathematics. The results are conclusive often presented in tables and graphs. It also investigates the what, where and when of decision making.

It finds applications not only in mathematics and physical sciences but also in social sciences, economics and biology.

- **Qualitative Research/Method:** Is deals with qualitative phenomenon involving or relating to quality. Qualitative research are descriptive, non numerical, applies reasoning and uses words; data cannot be graphed. It aims to get the meaning and describe the situation. It is exploratory and investigates the why and how of decision making. Investigation of the reasons for human behavior for example why people think or do certain things? To find why certain data are random then it is a qualitative research. If the aim is to investigate how random the data is, what is the mean, mode, variance and distribution function then it becomes quantitative. Explaining how absorption of drug takes place in our body is a qualitative description. It does not involve any numbers, quantities or data. While at how much or percentage drug is absorbed to blood; involves measurement of quantity hence it becomes quantitative Rajasekar, Philominathan and Chinnathambi, 2006; Kothari, 2004; Patil and Mankar, 2016; Borrego, Douglas and Amelink, 2009; Bernhard and Baillie, 2013; Choy, 2014).

RESEARCH APPROACHES

The generation of data in quantitative form which can be subjected carefully to quantitative analysis in a formal and fixed fashion is a quantitative approach. This approach can be further sub categorized into inferential, experimental and simulation approaches to research. Inferential approach leads to research that forms a data base from which to infer characteristics or relationships of population. This usually survey type research where a sample of population is studied (questioned or observed) to determine its features, and then to conclude that the population has the same features or charac-

teristics. Qualitative approach is concerned with subjective evaluation of opinions, attitudes and behavior. Research in such a situation is a function of researcher's perception and ideas or feeling. This generates results either in non quantitative form or in the form which are not subjected to accurate quantitative analysis.

Experimental approach is characterized by much greater control over the research variables and in this case some variables are manipulated to observe their effect and relation on other variables.

Simulation approach involves the setting up of an artificial environment within which relevant information or facts and data can be generated. This allows an observation of the dynamic behavior of a system under supervise state or controlled situations. (Kothari, 2004; Bhawna and Gobind, 2015).

RESEARCH PROCESS

Research process consists of series of steps as-

1. Formulation of Research Problem

At the very beginning, the researcher must decide the general area or field of interest or aspect of a subject matter that he would like to investigate or inquire into and then research problem should be formulated or prepared.

2. Extensive Literature Survey

For this purpose, the abstracting and indexing journals and published or unpublished bibliographies, academic journals, conference proceedings, government reports, books and internet search engine etc. must be utilized depending on the nature of the problem.

3. Development of Working Hypothesis

Working hypothesis is tentative postulations made in order to draw out and test its logical or empirical results.

4. Preparing the Research Design

After preparing hypothesis, research design or model (conceptual structure within which research would be conducted) is prepared. The framing of such a model helps to research to be as efficient as possible yielding maximal informative data. Research design provides collective relevant proof with ideal effort, time and expenditure.

5. Determining Sample Design

A designed sample plan is decided before any data or information is actually collected for obtaining a sample from a given population. Survey involves a great deal of time, money and energy so it is impossible in practice under many situations.

6. Collecting the Data

Primary data can be collected either through experiment work or through detail survey. In case of survey, data can be collected by any one or more ways like by observation, through personal interview, through telephonic interviews, by mailing of questionnaires or through schedules.

7. Execution of the Project

If the execution of the project proceeds on correct proper lines, the data to be collected would be sufficient and dependable.

8. Analysis of Data

The analysis of data has carried by a number of closely related operations such as establishment of categories coding, tabulation (based on the mathematical calculation of various percentages, standard deviations, coefficients etc.) and then drawing statistical inference.

9. Hypothesis Testing

After analyzing the data, the researcher should go to test the hypothesis, if any, he had prepared

earlier. Do the facts that support the hypothesis or they happen to be contrary? This is to be answered by applying various tests like 't' test, 'F' test, ANOVA etc. Testing will result in either acceptance or in rejection. If the researcher had no hypothesis or theory to start with, generalizations started on the basis of identified data.

10. Generalizations and Interpretation

If a hypothesis is tested and confirm several times, it may be possible for the researcher to reach at generalization that is to prepare a theory. As a matter of fact, the real value of research lies in its ability to reach at certain generalizations. If the researcher had no hypothesis to begin with, he might seek to explain his findings on the basis of some theory or facts. It is known as interpretation.

11. Preparation of the Report or the Thesis

Finally, the researcher has to prepare systematic report of what has been done by him (Rajasekar, Philominathan and Chinnathambi, 2006; Kothari, 2004; Gogoi and Goowalla, 2015; Pandey and Pandey, 2015; Kothari, 2004; Patil and Mankar, 2016).

IMPORTANCE OF RESEARCH

1. Research introduces scientific and rational new thinking, promotes the development of logical habits of thinking also governs the decisions of the policy maker.
2. Research has its special importance in solving various operational problems of business, society and industry.
3. Research helps for nearly all government policies in our economic system.
4. It helps in determination of motivations underlying the consumer (market) behavior.
5. It is important for social scientists in studying social relationships and in finding and solving various problems.

6. Research provides the intellectual satisfaction of knowing a few things just for the sake of knowledge; also practical use for the social peoples to know for the purpose of being able to do something better or in a more efficient manner than present.
7. To professionals research may mean a source of livelihood for philosophers and thinkers, research helps to outlet for new ideas, logics and insights.
8. Research is technique for the development of new styles and creative work makes it delightful and glorious.
9. Research is the base of knowledge to gain knowledge and an important source and guidelines for solving different types of problems in social, business and daily life (Rajasekar, Philominathan and Chinnathambi, 2006; Kothari, 2004).

RESEARCH METHODS AND RESEARCH METHODOLOGY

Research method includes all those methods or techniques that are used for conduction of research shown in Table 2 (Kothari, 2004). Research methods are essentially designed, scientifically formulated and value neutral. They include theoretical procedures, principles, hypothesis, experimental studies, numerical schemes and statistical approaches etc. Research methods help us collect samples, data and investigate a solution to an unsolved problem. Particularly, scientific research methods require explanations which are based on collected facts, information, experiments, measurements, observations and verification and not on reasoning alone. They accept only those explanations which can be confirmed by experiments.

Research methodology is a science of studying how research is to be carried out and is a systematic way to solve a problem. Various steps that are normally followed by a researcher in studying his/her research problem along with the scientific

Table 2. Method and techniques used to perform various researches (Kothari, 2004)

Types	Methods	Techniques
Library Research	1. Analysis of historical records	Recording of notes, Content analysis, Tape and Film listening analysis.
	2. Analysis of documents	Statistical compilations and manipulations, reference and abstract guides.
Field Research	1. Non-participant direct observation	Observational behavioral scales, use of score cards.
	2. Participant observation	Interactional recording, photo graphic techniques.
	3. Mass observation	Recording mass behavior, interview using independent observers.
	4. Mail questionnaire	Identification of social and economic background of respondents.
	5. Opinionnaire	Use of attitude scales, projective techniques, use of sociometric scales.
	6. Personal interview	Interviewer uses a detailed schedule with open and closed questions.
	7. Focused interview	Interviewer focuses attention upon a given experience and its effects.
	8. Group interview	Small groups of respondents are interviewed simultaneously.
	9. Telephone survey	Used as a survey technique for information and for discerning opinion; may also be used as a follow up of questionnaire.
	10. Case study and life history	Cross sectional collection of data for intensive analysis, longitudinal collection of data of intensive character.
Laboratory Research	Small group study of random behavior, play and role analysis	Use of audio-visual recording devices, use of observers, etc.

thought behind them. Thus it necessary for the researcher to know not only about the research methods/techniques but also the methodology. Researchers need to aware how to develop certain tests or indices, how to apply particular research techniques as well as they requires to know which of these methods or techniques are applicable and which are not. They should aware the criteria by which they can decide that certain methods, techniques and procedures will be applicable to solve certain problems and others will not. All this conclude that it is necessary for the researcher to design methodology for his/ her problem as the same may differ from problem to problem. (Rajasekar, Philominathan and Chinnathambi, 2006; Kothari, 2004; Gogoi and Goowalla, 2015; Kothari, 2004; Choy, 2014; <http://www.ais.utm.my/researchportal/files/2015/02/Example3-Res-Design.pdf>; Agbaje and Alarape, 2010; Khairul Baharein Mohd Noor, 2008).

CRITERIA OF GOOD RESEARCH

1. The aim should be clearly defined and common general concepts be used.
2. The procedure used should be described in sufficient detail to allow another researcher to repeat the research for further development, keeping the continuity of what has already been attained.
3. The designed procedure of the research should be carefully planned and thoroughly studied to obtain results that are as goal as possible.
4. The researcher should report with complete frankness, mark in procedural design and estimate their effects upon the investigating.
5. The analysis of data should be sufficiently satisfactory to show its importance and the methods of analysis used should be proper in the circumstances. The validity and reliability of the data should be checked and verified carefully.

6. Conclusions should be confined in area to those justified and explained by the data of the research and limited to those for which the data provide an adequate basis.
7. Greater confidence in research is justify if the researcher is experienced, has a good reputation in research and is a person of integrity.
8. In other words, we can express the good research should have characteristics such as systematic, logical, empirical and replicable (Pandey and Pandey, 2015; Kothari, 2004).

PROBLEMS ENCOUNTERED BY RESEARCHERS

1. The lack of a scientific training in the methodology of research is a great obstacle for researchers. There are small quantities of competent researchers. Research is mostly a scissor and paste job without any awareness shed on the collected materials.
2. There is insufficient or lack of interaction between the university research departments on one side and business establishments, government departments and research institutions on the other side, between researcher having same research interest.
3. Most of the business units do not have the confidence that the material supplied by them to researchers will not be misused and as such they are often resistant in supplying the needed information and data to researchers.
4. Research studies overlapping one another are undertaken completely often for want of sufficient information. This results in duplication and waste away resources.
5. There does not exist a code of conduct for researchers and inter university and inter-departmental competitions are also quite common.
6. Difficulty of sufficient and timely secretarial assistance, including computerial support. This leads to unnecessary delays in the completion and finalization of research studies.

7. Basic library management and functioning is not adequate at many places and much of the time and energy of researchers are spent in tracing out the books, journals, reports, and references etc. (Kothari, 2004).

FUTURE RESEARCH DIRECTIONS

Current Scenario of Research and Global Funding Forecast

The process of creating new products, processes and technologies that can be used and marketed for mankind's benefit in the future is termed as research and development (R&D). Asian countries continue to grow faster than other parts of the world. Because of this, combined Asian R&D investments are growing at a faster rate and their global R&D shares continue to increase at nearly 1% per year, while R&D shares of American and European decrease, even though their absolute R&D investments also continue to increase, but not at as fast rate as they do in Asia. Total global R&D share spending regional wise are shown in Table 3 (Global R&D funding forecast A supplement to R&D magazine, 2016).

The U.S. is largest single country in R&D investments with slightly more than a quarter of all global R&D spending. These U.S. R&D programs are supported and run by means of industrial (66%), federal government (25%) and academic/non-profit (7%) investments as shown in Figure 2 (Global R&D funding forecast A supplement to R&D magazine, 2016).

The global Life Science industry is one of the top large global high tech industries. It covers pharmaceuticals, biotechnology, medical devices and instruments, bioscience, veterinary, agricultural and commercial research and testing. However, most of the activities of these industries are operated in the biopharmaceutical sector by R&D, which reports for about 85% of the industries total R&D spending. Prediction shows a modest 1.8% increase in R&D spending for the global Life Science R&D marketplace in 2016 and a weak

Table 3. Share of total global R&D spending (Global R&D Funding Forecast A Supplement to R&D Magazine, 2016)

Region	Year		
	2014	2015	2016
North America	29.1%	28.5%	28.4%
U.S.	26.9%	26.4%	26.4%
Caribbean	0.1%	0.1%	0.1%
All North America	29.2%	28.5%	28.5%
Asia	40.2%	41.2%	41.8%
China	19.1%	19.8%	20.4%
Europe	21.5%	21.3%	21.0%
Russia	3.1%	2.9%	2.8%
South America	2.8%	2.6%	2.6%
Middle East	2.2%	2.3%	2.3%
Africa	1.0%	1.1%	1.1%
Total	100.0%	100.0%	100.0%

Figure 2. Country-wise share of R&D spending

Source: 2016 Global R&D funding forecast A supplement to R&D magazine

0.6% increase in U.S. R&D spending for 2016. (Global R&D funding forecast A supplement to R&D magazine, 2016).

Research on human being is very important for improvement of health and discovering new medicine and technology to treat diseases effectively. Current scenario of clinical trials revealed that there is a continuous increase in number of clinical research studies worldwide (about in 183 countries). Figure 3 shows registered numbers of clinical trials from the year 2007 to march 2015 on website www.clinicaltrials.gov.in. (Global R&D funding forecast A supplement to R&D magazine, 2016; Bangera, 2015).

World health organization (WHO), in U.S. National institute of health (NIH), National cancer institute (NCI) and Department of defense (DOD); in India Department of science & technology (DBT), Department of defense (DOD) and University of grant commission (UGC) etc are the research funding agency.

Information and Communication Technology (ICT) R&D are the backbone of the global digital economy and constitute a key driver of productivity growth in a knowledge-based economy and citizen's quality of life. It is clear fact that the ICT industry and ICT R&D innovation in non ICT industries and services make an important presence

to the economic growth of advanced economies. In the EU, USA and Japan; the ICT field is the largest R&D investing sector of the economy. The EU ICT sector is a significant contributor to achieving the target of investing 3% of GDP in R&D. When comparing ICT spending over GDP, the USA, Japan, Taiwan and Korea are investing significantly more in ICT R&D than the EU. Supporting the speedy pace of revolution in ICT requires high levels of R&D. Actually, in terms of R&D expenditures budget, patents, and venture capital investments; the ICT sector exceeds all other industries by a large margin.

For stronger development in ICT a new strategy was started, primarily to foster the commercialization of research such as policy governance, science base, business R&D and innovation, knowledge flows and commercialization, human resources, green innovation, clusters and regional policies and globalization (Giuditta De Prato, Daniel and Juraj, 2011; Stephen and Scott 2010; OECD, 2014).

CONCLUSION

Research is a systematic process of gaining new knowledge. Main aim of research is to find out the truth which hidden or not yet discovered.

Figure 3. Number of clinical trial studies registered worldwide
Source: 2016 Global R&D funding forecast A supplement to R&D magazine

Research mainly classified into to two groups as basic and applied research. Research process starts from formulating research problem to final report through systematic and accurate investigation. All research Approaches investigates and explore the different assert to knowledge and are designed to label a specific type of research problem.

The methods and procedures used by a researcher during a research study are the research methods. Research methodology is a science and systematic way of studying how research is to be carried out. It mainly provide plan of work for research. Good research should be systematic, logical, empirical and replicable. In some part researcher are facing problems during research because of lack of scientific knowledge and interaction and funding facility. Thus research introduces scientific and rational new ideas and it promotes the development of logical habits of thinking. Research has its special importance in solving various operational and planning problems of business, society and industry.

KEY TERMS AND DEFINITIONS

Applied Research: It deals with finding a solution or conclusion for an immediate problem by using well known theories or principles.

Basic Research: It deals with the finding the truth behind natural process or pure sciences problems.

Research: Finding the truth or solving the problem on the basis of scientific base is called as research.

Research Approaches: It define as the dealing of research by a particular manner or process.

Research Method: It includes all the procedure used to carry out research.

Research Methodology: It is way or path which shows how research is carried out in systematic manner.

Research Problems: It means that problems encountered during the research.

Scholarly Identity in an Increasingly Open and Digitally Connected World

Olga Belikov

Brigham Young University, USA

Royce Kimmons

Brigham Young University, USA

INTRODUCTION

The perceived role of the scholar has undergone rethinking in recent years as scholarly professionals have expanded conversations about the process of knowledge development and the role of the scholar in society. Boyer (1990) argues that “what we urgently need today is a more inclusive view of what it means to be a scholar – a recognition that knowledge is acquired through research, through synthesis, through practice, and through teaching” (p. 24), and he proposes that scholarship includes the four practices of discovery, integration, application, and teaching. In each of these aspects of scholarship, technology plays a role in defining possibilities, identifying priorities, and shaping practice, and advances in information technology over the past few decades have yielded significant technological artifacts (such as ubiquitous computing devices, data collection and storage systems, the internet, and social media) that influence what it means to be a scholar on an ongoing basis.

This chapter explores the intertwined relationship between technological advances and scholarly practice, and draws attention to emergent forms of scholarship described in the literature. The chapter will then highlight commonalities and differences between these emergent forms and discuss implications of the practices, especially those that affect the identity of the scholar as

they participate in these forms of scholarship. Throughout this conversation, technology will be used as an anchor for connecting scholarly practices to advances and social shifts of our time and will be treated as a co-evolutionary artifact with scholarship rather than as a change agent (cf. Veletsianos & Kimmons, 2012b).

BACKGROUND

As the historical centers of scholarly work for many centuries, universities have gradually developed and evolved in response to a variety of factors and are currently being reshaped in response to “globalization, mass expansion, and economic uncertainty, overlaid by new technologies connecting learners and content” and researchers “in new ways” (Siemens & Matheos, 2010, para. 17). Shifts in social norms and values and advances in technology have always impacted scholarship and the university, or institutionalized scholarship, in ways that reflect the needs and habits of the era (McNeely & Wolverton, 2008). Thus, when we consider emergent forms of scholarship connected to technology innovations, we must recognize that technology, society, and scholarship are all ever-evolving artifacts throughout all eras that influence and impact one another in complex and negotiated ways (Veletsianos & Kimmons, 2012b).

Some specific technologies that have historically impacted the creation and evolution of universities include the printing press, radio, television, microphotography/microfilm, mass publishing, microcomputers, the internet, and social media (Binkley, 1935; Tate, 1947; Siemens & Matheos, 2010; Veletsianos & Kimmons, 2012b). Each of these technologies bring with them different affordances, limitations, assumptions, and challenges that impact how scholars work in each of Boyer's areas of discovery, integration, application, and teaching. *Discovery* or the process of developing new knowledge through research is impacted as technologies improve efficiencies of data collection and analysis and allow for new methods of inquiry (e.g., big data, computational modeling). *Integration* is impacted as data and findings may be shared across distant locations and between experts within disciplines in a timelier manner. *Application* is influenced as scholars can more effectively report, serve, and collaborate with their communities, the public, and diverse colleagues from various disciplines. *Teaching* is impacted as scholars can teach students across geographic distances and employ new pedagogies and media to deliver instruction, assess student learning, and support student knowledge construction. *Identity* is impacted as scholars navigate their use of social medias and their offline and online identities converge while their sense of identities are impacted by their participation in these networks.

Forms of Emergent Technology-Influenced Scholarship

Many of the emerging scholarly practices that respond to recent technological advances associated with the internet and social media have been categorized into at least five general forms: *digital scholarship*, *social scholarship*, *open scholarship*, *public scholarship* and *networked participatory scholarship* (Kimmons, 2015). Each of these identified forms seeks to draw attention to a set of scholarly practices (or in some cases to advocate

for those practices) in contradistinction to previous norms in the following ways:

- **Digital Scholarship:** Emphasizes the power of the internet and digital media for making data sharing and collaboration cheaper, faster, and easier (Andersen, 2003; Borgman, 2007; Pearce, Weller, Scanlon, & Kinsley, 2010; Russell, Weinberger, & Stone, 1999).
- **Social Scholarship:** Highlights the importance of social interaction between scholars to generate quality work and to induct new scholars into academe by utilizing computer-mediated mechanisms like discussion groups (Berge & Collins, 1995), blogs (Chong, 2010), and social networking sites (Greenhow, 2009) to support scholarship that is conversational and less formal than the traditional publication cycle (Oblinger, 2010).
- **Open Scholarship:** Emphasizes the importance of utilizing technologies and practices for teaching and research that espouse openness and sharing for the purpose of broadening access to knowledge, reducing costs, enhancing scholarly impact, and supporting transparent and equitable practices (Furlough, 2010; Wiley & Green, 2012; Eysenbach, 2006; Norris, Oppenheim, & Rowland, 2008; Veletsianos & Kimmons, 2012a, para. 3).
- **Public Scholarship:** Articulates the importance of public participation by scholars as an obligation to the community and a desire to stay relevant in their respective fields through civic engagement (Brown-Dean, 2015).
- **Networked Participatory Scholarship:** Builds off of the three aforementioned forms of scholarship and attempts to bring them together into a unified vision of scholars using digital and social technologies to “share, reflect upon, critique, improve,

validate, and further their scholarship” in ways that fundamentally transform existing institutional structures (Veletsianos & Kimmons, 2012b).

COMMONALITIES AND DIFFERENCES

These emergent forms of scholarship are not mutually exclusive nor clearly delineated but rather represent a collection of connected emerging practices evolving with a variety of technologies, and at least three of the terms have been proposed to only understand or to promote a subset of emergent practices. If we consider all five categorizations and look for common themes across them, we discover some commonalities surrounding the ideas of *digitization*, *sharing*, *democratization*, *social networking*, and *transparency*. These themes are interconnected, and each deserves focused attention for us to recognize the richness of emergent forms of scholarly practice.

- **Digitization:** Refers to the transfer of scholarly artifacts and processes from previous media formats (e.g., print journals, letters, catalogues) to digital formats (e.g., electronic media, online journals, emails, databases). The process of digitization provides many opportunities for improved efficiency and access to scholarly work both for dissemination and collaboration. For example, database technologies allow for the collection, storage, manipulation, analysis, and retrieval of large datasets for research, which has given rise to a wide array of new interdisciplinary fields and profitable research lines. Through the use of shared databases and other digital technologies, the speed and scale at which research may be conducted has increased. All five identified categorizations rely upon digitization and are empowered by it, and without digital media and artifacts that

improve connections, sharing, and efficiencies, we would not be able to explore new forms of scholarship that rely upon information processing, social connections at a distance, and inexpensive publishing and sharing mechanisms.

- **Sharing:** Of data has improved through digitization as well and represents a common theme from all five categorizations. Large datasets can be collaboratively constructed and analyzed by geographically dispersed researchers and shared with scholars from various fields via online portals and other mechanisms. This sharing allows for improved collaboration and interdisciplinary scholarship, as traditional institutional and departmental boundaries are breached or bypassed. Sometimes referred to as primary source sharing, improved access to data sources allows for new types of questions to be asked and research lines to be explored as scholars can combine datasets from and easily bring in experts from a variety of fields to collect and analyze data.

This sharing extends to improved dissemination of findings, research outcomes, reviews, and scholarly opinion, or secondary sources. By publishing findings in online journals and less formal online venues (e.g., discussion fora, blogs), researchers allow their work to be indexed by online catalogs and search engines and to be accessible by researchers throughout the world, thereby circumventing many persistent problems of access to academic material. This improved access gives researchers greater facility to stay abreast of new findings, review peers' work, and to provide responses in a timely manner. Due to the nature of digital media, which can be disseminated and stored at relatively low costs, new sharing possibilities are also available through the innovation of open access journals, and scholars can engage in a variety of practices that are open, social, and networked.

These approaches to collaborating, sharing findings, and reducing or removing traditional barriers to dissemination may have the potential to *democratize* some aspects of the scholarly enterprise by allowing a greater number and diversity of scholars to contribute to research endeavors and to gain access to findings and discussion. Whereas it may be that the establishment of the university at the center of scholarly work occurred in large part due to mass publication and the inability of individuals and smaller institutions to keep pace with large entities' collection and storage of scholarly artifacts (Binkley, 1935), the reduction of these barriers may lead to a rethinking of the role of universities in society and scholars' relationships to them. As physical barriers are removed through the replacement of many traditional libraries with online resources and monetary barriers are removed through the growth of open access journals and other scholarly portals, collaboration and access of scholarly work will likely increasingly occur in virtual spaces rather than geographic locales, which has the impact of increasing access and participation across traditional geographic barriers but also calls into question the usefulness or necessity of many geographically bound sites of scholarly endeavor.

- **Social Networking:** Also influences sharing and dissemination by connecting the networked lives of scholars with their work. Emphasized in social scholarship, public scholarship, and networked participatory scholarship, each scholar has social connections that reflect personal and professional relationships, and scholars' literacies to traverse these connections, develop new relationships, and present meaningful online personas can influence their abilities to conduct meaningful work, share findings, and find and utilize available resources. By using an informal sharing space like a blog, for instance, scholars can share their work with colleagues and the public through all stages of the scholarly

process and elicit feedback or solicit partnerships to improve their work. Similarly, scholars can nurture online relationships through a social networking platform and quickly gain access to a wealth of suggestions regarding research questions, data sources, previous work, funding and job opportunities, and so forth and can quickly gain insight from a variety of people even outside of their field, thereby potentially improving interdisciplinary work. These social networking sites, especially Twitter, have become increasingly prevalent in professional settings as scholars use Twitter as a conference backchannel and a professional networking platform (Kimmons & Veletsianos, under review; Veletsianos, 2012). The wide variety of social networking sites allows scholars to contribute meaningfully to the public sphere both formally and informally.

- **Transparency:** Plays a role in these practices as well, as information is diffused freely and scholars' relationships, thoughts, opinions, and interactions take an increasingly public stage, thereby opening more aspects of their lives to both scrutiny and celebration (Tufekci, 2008). Open scholarship emphasizes the importance of removing barriers between learners and content and between learners and teachers, and for scholars to effectively connect with others socially online requires for them to be transparent in what they share (Dalsgaard & Paulsen, 2009; Mazer, Murphy, & Simonds, 2007). As scholars begin to remove these barriers, they participate in public scholarship and are able to engage in public spheres of their expertise. Such transparency suggests fundamental shifts in the nature of academic institutions and the roles that scholars play in society and may suggest shifts in thinking of scholars less like laboratory-dwelling recluses to micro-celebrities (Marwick & boyd, 2011).

Throughout these discussions, some scholars approach these issues with an interest in utility and focus on technologies' affordances to improve efficiency and scale. However, other scholars, as with open scholarship, take a social advocacy stance and argue that there are moral considerations to supporting forms of technology-enhanced scholarship that are democratized or transparent. Such fundamental shifts in thinking and emphases upon advocacy bring with them certain difficulties and implications that require attention.

Democratic participation in the scholarly process, as with the political process, requires certain literacies, skills, and attitudes and an allotment of time on the part of participants. Thus, though barriers to entry may be reduced in terms of geography and overt monetary constraints, other factors may influence an individual's or institution's ability to effectively participate in these new forms of scholarship, suggesting that barriers may not be altogether removed but rather changed to favor new groups of scholars (Veletsianos & Kimmons, 2012a). As has been pointed out in discussions of the public domain, the openness of any domain (e.g., the internet) favors those with the resources and skills necessary to gain advantage from it (Chander & Sunder, 2004). In terms of resources, those individuals and institutions with the infrastructure necessary to support sustained access and sharing (e.g., networks, data sources) and those who have developed the skills necessary to develop and utilize social networks and to traverse massive amounts of information will gain greater advantage from these technologies. This conversely means that scholars who lack valuable social connections in the real world may have difficulty creating and sustaining new social relationships online and that traditional problems of inequity may be replicated in online spaces (cf. Thelwall, 2009, and the problem of homophily).

Democratic participation also requires participants to be well-informed and to have access to dissenting views.

DIFFICULTIES AND IMPLICATIONS

R

However, two problems have arisen in conjunction with the advent of the social and semantic webs, which pose problems for emerging scholarly practice. The social web, or Web 2.0, allows participants to connect with like-minded individuals via social media and social networks, to create and remix content, and to share content with the world. Because users of social media readily connect only with those that they agree or have some other social connection with, this creates a situation in which online echo chambers emerge and scholars naturally isolate themselves from dissenting opinion (Gilbert, Bergstrom, & Karahalios, 2009). Consider a blog that a scholar uses to share work in progress to solicit feedback. If this blog is followed by like-minded scholars, this can lead to authors only interacting with those who already share their opinions and may have the effect of minimizing or ignoring dissenting views.

Similarly, the semantic web, or Web 3.0, relies upon machine algorithms to present information to users that is relevant to their interests and requirements. As scholars utilize search engines and other mechanisms for navigating web content, filter bubbles can emerge in which a scholar's traversal of online resources is effectively managed to only deliver supporting viewpoints and similarities in thinking (Pariser, 2011). This means that if scholars are looking for evidence to support their work, they can more easily find it and not have to sift through dissenting or irrelevant evidence in the process.

Both of these examples have deep implications for scholarly practice, because though critique and controversy have traditionally been valuable hallmarks of scholarship, emerging practices may lead to scholars operating within new forms of insulation and isolation. Whereas scholars have traditionally been viewed as largely operating within the "ivory tower" of an academic institution that may be disconnected from the problems and

realities of the world at large, social technologies can both supplant these barriers by increasing communicative efficacy with those outside the institution but simultaneously instantiate new barriers based upon the social relationships, beliefs, and values of the scholar. In these new forms of scholarship, then, it behooves scholars to consider the value of dissenting viewpoints and to utilize new technologies in a manner that allows them to meaningfully grow, develop, and work within a diverse global community.

There is also the prevailing issue of identity fragmentation that is affected by all of these forms of scholarly participation. Identity can be understood as a constellation of interconnected fragments of social participation (Kimmons & Veletsianos, 2014). As scholars seek to be participatory and interact with these emergent technologies, they encounter incongruencies between their values and opinions and those of the general public. When it comes to sharing, the scholar may be inclined to share something that is of value to them but may be perceived by institutions, fellow scholars, or students as inappropriate material for a public forum. These blurred lines between the personal and professional sharing done by scholars is largely in part due to the pluralistic use of blogs, social medias and other forms of sharing. With greater potential for interaction, issues of privacy are raised (Lin, Hoffman, & Borengasser, 2013). Social networking sites are used to support educational endeavors, but there is little precedence for scholars to adhere to when it comes to use of these sites. The identity of the scholar participating in social networking sites is rarely an entirely authentic or complete representation of the scholar's identity due to issues of implicit and explicit appropriate uses of these media. The ideal of democratization through networked participatory scholarship may be turned upside down as scholars begin to be wary of participating in the public sphere for fear of scrutiny. Scholars

may then be inclined to turn inwards and remove themselves from the democratic ideals that public and open scholarship promote. Although using these networking tools as scholars can be valuable and can nurture beneficial scholarly relationships, the effects of the convergence between offline and online personas may influence the representational identity of the scholar to the point that it may become fragmented and disjointed from the true identity of the scholar (Kimmons & Veletsianos, 2014). This fragmented and incomplete identity may hinder the scholar from using these social networking sites as a means of truly meaningful social participation.

FUTURE RESEARCH DIRECTIONS

There is a great deal of ambiguity surrounding what appropriate and meaningful participatory scholarship looks like. Without a deeper understanding of how scholars can participate in the public sphere in the most impactful way possible while still preserving their values and those of their institution, they will not be able to contribute meaningfully. It would be valuable to conceive a flexible and plural framework for what networked participatory scholarship should look like. While some of these more specific forms of scholarship such as open scholarship have some prescriptions for optimal participation, the dependence that networked participatory scholarship has upon the value system of the scholar leaves room for discussion regarding guidelines for this type of participation. More specifically there is also the need to analyze what prescriptions institutions are making for the scholars and whether they are held to the standards of explicit or implicit assumptions of acceptable behavior.

The framework of the acceptable identity fragment as it applies in higher education is another area that needs to be looked at more closely.

While the idea of identity fragmentation has been valuable in discussing networked participation across educators of younger ages, it is important to inspect this framework to understand whether this identity fragment truly applies in higher education. The way in which scholars engage in the public sphere is very unique in comparison to other educators and understanding the way in which scholars interact with identity fragmentation needs to be further explored and understood. Along with other educators, there is also a significant amount of teachers using these forms of public participation and social networking in their classroom (Piotrowski 2015). It is crucial that as these medias become widespread as teaching tools, that we recognize the implications that come with classroom use of these tools. A deeper analysis of identity, power relationships, and community perception is vital and as some of these aspects of public participation are better understood, there may be hope for a guide of how scholars approach networked participation in both formal and informal settings.

CONCLUSION

In this chapter, we see that emerging scholarly practices extend existing practice but also stand to continually reshape it, generating new efficiencies, possibilities, and challenges. Clear identification of all emerging practices is difficult, but the literature suggests at least five general emergent forms that include a wide range of technology-influenced scholarly practices, namely: digital scholarship, social scholarship, open scholarship, public scholarship, and networked participatory scholarship. Scholarly practice has historically evolved with technology and other cultural artifacts, and these categorizations of emerging scholarly practice serve to draw attention to a set of interconnected themes permeating the literature that may help guide us to meaningfully direct the ever-morphing forms that scholarship continues to take in our time.

KEY TERMS AND DEFINITIONS

Digital Scholarship: An emergent form of scholarship that emphasizes the use of digital technologies to support efficiency.

Networked Participatory Scholarship: An emergent form of scholarship that emphasizes the role that social technologies play in reshaping educational institutions and the role of the scholar.

Open Scholarship: An emergent form of scholarship that emphasizes openness, sharing, and democratization of educational resources.

Public Scholarship: An emergent form of scholarship that emphasizes responsibility of the scholar to engage in the public sphere.

Social Scholarship: An emergent form of scholarship that emphasizes the importance of collaboration and mentoring in the scholarly process.

Risk Assessment

Fuzzy Logic Approach in Risk Assessment

R**Çetin Karahan***Directorate General of Civil Aviation, Turkey***Esra Ayça Güzeldereli***Afyon Kocatepe University, Turkey***Ashlhan Tüfekci***Gazi University, Turkey*

INTRODUCTION

As an intuitively subjective and ambiguous notion, risk requires a detailed and attentive study, though. Since risk involves the events likely to occur in the future, risk assessment is an area where uncertainty is prevalent. Therefore, making use of experience, previous statistics and prediction ability is crucial in risk studies. The field of risk management is enriched with new techniques and methodologies, which serve the purposes of discovering more data, reducing subjectivity through more quantitative models and building flexible systems conducive to be updated with the obtained data. One of these new tools is fuzzy logic representing the uncertainty and to study with imprecise and uncertain knowledge.

This paper discusses the application of fuzzy logic to risk assessment process as an alternative to the traditional models due to its similarity to human reasoning and its accuracy in interpreting uncertainty. A fuzzy logic-based algorithm is developed for the purposes of enhancing risk assessment accuracy. Impact and likelihood factors, which are fundamental elements of risk, measured by the fuzzy logic-based approach. Beyond the impact and likelihood values, the factors directly effecting impact and likelihood also considered in this study and these factors included in fuzzy operations, in order to reduce subjectivity and increase precision.

In this study, an approach is explained for risk assessment. The aim of this approach is providing insight as a powerful alternative to traditional methods. A comparison between the risk values measured by the new model and those measured by the classical model supports the view that using fuzzy logic in risk assessment helps to produce more effective outcomes.

BACKGROUND

The concept of fuzzy logic was first introduced in 1965 by Prof. Lotfi A. Zadeh who developed Lukasiewicz's multivalued logic to set theory and created what he called fuzzy sets – sets whose elements belong to it in different degrees. At the start, fuzzy logic was a theoretical concept with little practical application. In the 1970's, Prof. Edrahim Mamdani of Queen Mary College, London, built the first fuzzy system, a steam-engine controller, and he later designed the first fuzzy traffic lights. His work led to an extensive development of fuzzy control applications and products (Cirstea, Dinu, McCormick & Khor, 2002, pp. 113-114).

Bellman and Zadeh (1970) developed an initial general theory on decision making in fuzzy environment which include three basic concepts as fuzzy goals, fuzzy constraints and fuzzy decisions. It is concluded that the proposed theory is generally has advantages according to the traditional probability theory.

DOI: 10.4018/978-1-5225-2255-3.ch588

Tah and Carr (1999) claimed that the current risk management techniques mostly based on the operational research techniques developed in 1960s and usually had failed to meet the needs of project managers. They introduced a fuzzy risk analysis model for a construction project to eliminate the past studies' concentration on particular risks and proposed a model which have a generic and generally practicable representation.

The development of fuzzy set theory to fuzzy technology during the first half of the 1990s has been very fast. More than 16,000 publications have appeared since 1965. Most of them have advanced the theory in many areas. Quite a number of these publications describe, however, applications of fuzzy set theory to existing methodology or to real problems. In addition, the transition from fuzzy set theory to fuzzy technology has been achieved by providing numerous software and hardware tools that considerably improve the design of fuzzy systems and make them more applicable in practice (Zimmerman, 2001, p. xxi).

Hajiha, Roodposhti and Askary (2009) provided a risk assessment approach conducted on the basis of fuzzy logic for audit risk, inherent risk and control risk. The results are compared to a real case and the accuracy level of the results is discovered to be relatively higher.

Keropyan and Gil-Lafuente (2011) place the emphasis on the importance of the ability of making right decisions and provide examples of use of fuzzy logic in selection of the decision-making styles within the scope of strategic management.

A. Pesic, D. Pesic and Tepavcevic (2012) proposed fuzzy logic as an innovative strategic management instrument to identify internal risks and to eliminate some of the restrictions imposed by the classical methods.

Nunes and Marques (2012) developed a fuzzy logic-based model for using in risk assessment of work accidents and occupational diseases and discussed the superiority of the fuzzy logic over the classical methods arguing that it allows a more comprehensive evaluation of risks and combination of both subjective and objective criteria.

Dainiene and Dagiliene (2013) calculated the sustainability of the business by using fuzzy logic and the competence of the business was shown experimentally. In the study, the operational value of the business is calculated on the basis of the financial and non-financial data.

Shang and Hossen (2013) provided evidence for the possible use of fuzzy logic as a decision-making system. The study supports the view that fuzzy logic may also be used in complex risk systems along with the other risk models such as decision trees and artificial neural network.

All of the studies that have been investigated support the view that the use of fuzzy logic as a decision-making system in strategic management has a number of advantages particularly in situations where there is a high level of unclarity.

USING FUZZY LOGIC TO IDENTIFY THE LEVEL OF RISK

General Information on Fuzzy Logic

The concept in question is that of a fuzzy set, that is, a "class" with a continuum of grades of membership. As will be seen in the sequel, the notion of a fuzzy set provides a convenient point of departure for the construction of a conceptual framework which parallels in many respects the framework used in the case of ordinary sets, but is more general than the latter and, potentially, may prove to have much wider scope of applicability, particularly in the fields of pattern classification and information processing. Essentially, such a framework provides a natural way of dealing with problems in which the source of imprecision is the absence of sharply defined criteria of class membership rather than the presence of random variables (Zadeh, 1965, p. 339).

In short, fuzzy set is a set where the members of the universal set have appointed values between the closed range of 0-1 and their membership status and membership degrees can be identified by these appointed values. The following should be taken into consideration while forming fuzzy sets:

- Fuzzy sets which are marked in the universal set need to be distributed symmetrically.
- The number of fuzzy sets defined for each variable should be odd number (typically 3, 5 or 7). Thus, some fuzzy sets may remain in the middle. Here, as an example, for temperature value it can be defined 3 fuzzy sets with cold, warm and hot values.
- For providing each value being defined, fuzzy sets should be overlapped to each other with a certain percentage. This will ensure the execution of more than one rule in the process of determining the output.
- Triangle or trapezoidal membership functions had better to be selected, which take less time to compute.

Kulkarni (2001) identifies Fuzzy Inference Systems (FIS) as a tool using if-then rules to state the relation between the input and output fuzzy sets. Fuzzy relations indicate the degree of existence or non-existence of the links and the interactions between the members of one or several sets.

While a fuzzy system is designed, system inputs and outputs are identified and fuzzy sets are built for each input and each output. Relationship between these sets of input and output are built through logical processes. Fuzzy logic system converts these verbal statements into numerical statements and generates a single value at the end.

Risk and Risk Management

Risk is the combination of the likelihood and the consequence of a specified hazard being realized. The type of risk analysis used should be appropriate for the available data and to the exposure, frequency and severity of potential loss. Quantitative risk analysis incorporates numerical estimates of frequency or probability and consequence. In practice a sophisticated analysis of risk requires extensive data which are expensive to acquire or often unavailable (Pokoradi, 2002, p. 64).

Because it facilitates the exploration of the effects of the decisions made, actions of prioritization, mitigation and measurement, risk assessment

is a mechanism which helps a great deal with organizational stability.

Risk management is an iterative and cyclic process whose main aim is to eliminate or at least to reduce the risks according to the ALARP (as low as reasonably practicable) principle. (Nunes & Marques, 2012, p. 22).

Traditionally, probability theory was one of the methodologies used most in risk assessment. Probabilistic risk assessment (PRA) is the general term for risk assessment that uses theory and models to represent the likelihood of different risk levels in a population (i.e. variability) or to characterize the uncertainty in risk estimates. Among various probabilistic techniques to quantify uncertainties, the most widely used approach has been Monte-Carlo analysis (MCA) (Darbra, Eljarrat & Barcelo, 2008, p. 379).

One of the most frequently conducted methods is the matrix method. Risk values are obtained by multiplying likelihood of occurrence value by impact value. Risk values are classified as low, moderate and high and the value range for each classification is determined according to the preferred scale. Below is an example of impact-likelihood matrix.

Fine-Kinney method and fault-tree analysis also popularly used tools for risk assessment. Fuzzy logic approach, has recently come forward as a big contributor to the studies on risk assessment. A superior approach to model situations where there is a substantial amount of uncertainty, fuzzy logic is capable of incorporating human reasoning and judgment into the system.

Designing Fuzzy System

The factors directly effecting the likelihood and impact of an event are selected to use their scores in fuzzy calculations to generate an impact and a likelihood output value. These two output values of impact and likelihood are then become the inputs of the final FIS which generates a risk score. In this sense, fuzzy logic operates on three different systems rather than only one as illustrated in Figure 2.

Figure 1. Example of impact- likelihood matrix used in risk assessment

Figure 2. Fuzzy Inference System for risk assessment

The design of fuzzy system involves manually created fuzzy sets, functions and if-then rules as well as Fuzzy Logic component of MATLAB 7.0 program. Hence, the system can be converted to a software with any programming language easily by using these manually created and expressed fuzzy system components. MATLAB 7.0 is used to verify the calculations that are done manually.

Fundamental properties of the designed FIS:

Type : Mamdani

“and” Method : min

Defuzzification Method : centroid

Implication Method : min

Aggregation Method : max

Impact Likelihood Risk

Input : [1x2] [1x2] [1x2]

Output : [1x1] [1x1] [1x1]

Rule : [1x9] [1x9] [1x25]

A numerical example also embedded in the FIS explanations steps. The example includes impact and likelihood factors' scores which supposed to be generated by expert opinions. In order to testify the flexibility and accuracy of the fuzzy logic system, the example uses decimal values, which would otherwise be integer¹. The numerical inputs for the example is as follows:

Impact Factors' Scores Are: Financial = 7,5
and Reputation = 6,4

Likelihood Factors' Scores Are: Complexity = 7
and Workload = 6

Table 1. Scoring criteria for the risk-related impact factor

Impact Factor	Score	Expression	Damage (USD)
Financial loss (likely to occur)	1	Too low	< 3.000
	2	Too low	3.000 – 10.000
	3	Low	10.000 – 17.000
	4	Low	17.000 – 34.000
	5	Moderate	34.000 – 67.000
	6	Moderate	67.000 – 117.000
	7	High	117.000 – 167.000
	8	High	167.000 – 250.000
	9	Too high	250.000 – 333.000
	10	Too high	> 333.000
			Damage expression
Reputational damage (likely to occur)	1	Too low	only at the level of the concerned stakeholders
	2	Too low	only at the level of the stakeholders involved
	3	Low	being in the news in local printed media
	4	Low	being in the news in local printed and visual media
	5	Moderate	being in the news in local and regional printed media
	6	Moderate	being in the news in local and regional printed and visual media
	7	High	being in the news in national printed media
	8	High	being in the news in national printed and visual media
	9	Too high	being in the news in international printed media
	10	Too high	being in the news in international printed and visual media

Design of Impact and Likelihood FISs

Step 1: Identifying Input Data Set and Linguistic Variables

In case a risk occurred, there might be a number of subsequent social, economic, reputation and legal impacts. In this study only two of the factors were considered as inputs (financial and reputation impact). Input values were constructed on the basis of certain criteria, which are shown in Table 1.

The likelihood of a risk occurring depend on several factors such as workload and complexity of the process, the extent to which information technologies are used and the quality of the human resources. This study is concerned with only two factors as input: complexity and workload. The criteria determined for these values are shown in Table 2.

The criteria specified in above tables are configured to allow for the expert opinion to be included in the basis of fuzzy logic processes.

Step 2: Generating Membership Functions

Below are the membership functions built for the impact and likelihood fuzzy systems.

Table 3. Financial Impact membership functions

Condition	Membership Degree	Fuzzy Set
$0 < fI \leq 2$	$fI_{md} = 1$	Low
$2 < fI \leq 4$	$fI_{md} = \frac{4 - fI}{2}$ $fI_{md} = \frac{fI - 2}{2}$	Low Moderate
$4 < fI \leq 6$	$fI_{md} = 1$	Moderate
$6 < fI \leq 8$	$fI_{md} = \frac{fI - 6}{2}$ $fI_{md} = \frac{8 - fI}{2}$	High Moderate
$8 < fI \leq 10$	$fI_{md} = 1$	High

where fI_{md} indicates the membership degree of financial impact.

By referencing Figure 3, the membership functions for “financial impact (fI)” factor are generated as follows (see Table 3).

Since the functions for the financial and reputation impact are the same, the graphs and the formula for the reputation impact are not provided separately. As can be seen from the Figure 4,

Figure 3. Graph showing the membership functions for financial and reputation impact

Table 2. Scoring criteria for the risk-related likelihood factor

Complexity (Assesses whether the complexity of the operations or the relevant legislation impedes the exercise of the controls, thereby increasing the likelihood of faults.)	
1	Operation/legislation isn't complex, fault likelihood is TOO LOW.
2	Operation/legislation isn't complex, fault likelihood is TOO LOW.
3	Operation/legislation isn't quite complex, fault likelihood is LOW.
4	Operation/legislation isn't quite complex, fault likelihood is LOW.
5	Operation/legislation is somewhat complex, fault likelihood is MODERATE.
6	Operation/legislation is somewhat complex, fault likelihood is MODERATE.
7	Operation/legislation is complex, fault likelihood is HIGH.
8	Operation/legislation is complex, fault likelihood is HIGH.
9	Operation/legislation is excessively complex, fault likelihood is TOO HIGH.
10	Operation/legislation is excessively complex, fault likelihood is TOO HIGH.
Workload (Assesses whether the understaff in face of the workload increases the likelihood of faults)	
1	The number of staff is adequate to perform the workload.
2	The number of staff is adequate yet the staff is inexperienced to perform the workload.
3	The number of staff is hardly adequate to perform the workload.
4	The number of staff is only adequate to perform the workload with extra effort and time.
5	The number of staff is seldomly inadequate to perform the workload.
6	The number of staff is sometimes not adequate to perform the workload.
7	The workload is high for the number of staff. Work is completed with short delay.
8	The workload is high for the number of staff. Work is completed with substantial delay.
9	The workload is too high for the number of staff. Some work is incomplete.
10	The workload is too high for the number of staff. Substantial amount of work is incomplete.

Figure 4. Graph showing the membership functions for the complexity and workload likelihood factors

Table 4. If-then rules for “Impact”

		Financial Impact		Reputation Impact		Impact
1	IF	Low	&	Low	THEN	Too low
2		Low		Moderate		Low
3		Low		High		Moderate
4		Moderate		Low		Low
5		Moderate		Moderate		Moderate
6		Moderate		High		High
7		High		Low		Moderate
8		High		Moderate		High
9		High		High		Too high

the membership functions for likelihood factors (complexity and workload) would be the same with Table 3 entries.

In this regard, the financial impact (fI) value of 7,5 coincides with the range of 6-8 in the membership degree functions provided. Therefore;

$fI_{md} = (7,5 - 6)/2 = 0,75$ (high) - 75% “high” set member,

$= (8 - 7,5)/2 = 0,25$ (moderate) - 25% “moderate” set member.

In a similar way, as the reputation impact (rI) value of 6,4 is in 6-8 interval:

$rI_{md} = (6,4 - 6)/2 = 0,2$ (high) - 20% “high” set member,

$= (8 - 6,4)/2 = 0,8$ (moderate) - 80% “moderate” set member.

The complexity likelihood (cL) value of 7 coincides in 6-8 interval in the membership degree functions provided. Therefore;

$cL_{md} = (7 - 6)/2 = 0,5$ (high) -50% “high” set member,

$= (8 - 7)/2 = 0,5$ (moderate) -50% “moderate” set member.

Table 5. If-then rules for “Likelihood”

		Complexity		Workload		Likelihood
1	IF	Low	&	Low	THEN	Too low
2		Moderate		Low		Low
3		High		Low		Moderate
4		Low		Moderate		Low
5		Moderate		Moderate		Moderate
6		High		Moderate		Too high
7		Low		High		Moderate
8		Moderate		High		High
9		High		High		Too high

Table 6. Fuzzy rule strength for the numerical example with the nonzero value

Rule Num.	fI_{md}	rI_{md}	Rule Strength (min)	Impact
5	0,25	0,8	0,25	Moderate
6	0,25	0,2	0,2	High
8	0,75	0,8	0,75	High
9	0,75	0,2	0,2	Too high

As the workload likelihood (wL) value of 6 coincides in 4-6 interval

$wL_{md} = 1$ (Moderate) - 100% “moderate” set member.

Step 3: Rule Base

Once the inputs were constructed, output membership functions (Figure 5) are developed in the

fuzzy system and then if-then rules are determined. If-then rules, which allow association between the inputs and the outputs for the impact and likelihood factors are provided below.

Step 4: Application of Fuzzy Operators

As both impact factors are the members of the 2 fuzzy sets (“high” and “moderate”) there would be $2 \times 2 = 4$ rules with nonzero value (see 5, 6, 8 and 9th lines in Table 4). Following the selection of the rules, strength of each rule is calculated. The strength of a rule implies its lowest or weakest value (minimum). Table 6 indicates the rule strengths for each nonzero valued rules.

As one of the likelihood factors is a member of “1” set and the other is “2” sets, there appear $2 \times 1 = 2$ rules which are nonzero (see 5 and 6th lines in Table 5). The fuzzy rule strength for the example with the nonzero value is shown in Table 7.

Table 7. Fuzzy rule strengths for the numerical example with the nonzero value

Rule Num.	cL_{md}	wL_{md}	Rule Strength (min)	Likelihood
5	0,50	1	0,50	Moderate
6	0,50	1	0,50	Too High

Figure 5. Output membership functions for the impact and likelihood factors

Table 8. Impact/likelihood output fuzzy sets' area formulas and centroid values

Fuzzy set	Area	Centroid (x;y)	Centroid
Too Low	$\frac{(4x - x^2)}{2}$	$\left(\frac{(x_1 + x_2 + \dots + x_n)}{n}, \frac{(y_1 + y_2 + \dots + y_n)}{n} \right)$	0,75
Low	$\frac{(6x - 3x^2)}{2}$		2,5
Moderate	$4x - x^2$		5
High	$\frac{(6x - 3x^2)}{2}$		7,5
Too High	$\frac{(4x - x^2)}{2}$		9,25

where x indicates a single value generated by FIS.

Step 5: Output Membership Functions for Impact and Likelihood Factors (Defuzzification)

Output membership functions, given in Figure 5, are constructed in the same way as the input membership functions. In this study, the outputs for the impact and likelihood factors are expressed as “too Low, Low, Moderate, High and too High”.

Shown below are the area formula for and the centroid² value of the impact and likelihood output membership functions given in the figure above (see Table 8). These formulas and values will eventually be used during defuzzification, which is the final process.

In this stage, using the acceptable rules (those with values other than 0), aggregation process conducted. As in Table 6, more than one rule set may share the same result or system output. Where this is the case, the output which is “the most real” or

“the strongest” (with the maximum value) will get appointed. Among the rules producing the same results, the ones with the maximum strength are selected from Table 6 to form Table 9.

In the same manner, the values received from Table 7 is as follows (see Table 10).

These threshold values will be cited for the area calculation using the system output graph. Below is the table showing the area values calculated for each system output using the values provided above (see Table 11).

As a consequence of the defuzzification process, the impact and likelihood scores are calculated to be 6,86 and 6,38 respectively. In order to verify this manual calculation, the same input values are also executed by the MATLAB program. The impact and likelihood values produced by MATLAB stands at 6,86 and 6,41 respectively as well.

Table 9. Fuzzy set threshold values for the numerical example (impact)

Too Low	Low	Moderate	High	Too High
-	-	0,25	0,75	0,2

Table 10. Fuzzy set threshold values for the numerical example (likelihood)

Too Low	Low	Moderate	High	Too High
-	-	0,50	-	0,50

Table 11. Fuzzy membership functions area values for the numerical example

Fuzzy Set	Area	Impact				Likelihood			
		x	Area	Centroid	(Area x Centroid)	x	Area	Centroid	(Area x Centroid)
Too Low	$\frac{(4x - x^2)}{2}$	0	0	-	0	0	0	-	0
Low	$\frac{(6x - 3x^2)}{2}$	0	0	-	0	0	0	-	0
Moderate	$4x - x^2$	0,25	0,9375	5	4,6875	0,50	1,75	5	8,75
High	$\frac{(6x - 3x^2)}{2}$	0,75	1,40625	7,5	10,54688	0	0	-	0
Too High	$\frac{(4x - x^2)}{2}$	0,2	0,38	9,05	3,439	0,50	0,875	9,125	7,984375
SUM			2,72375		18,67338		2,625		16,73438
$\frac{\sum((centroid)_i x (area)_i)}{\sum (area)_i}$		6,855761				6,375			

Design of Risk FIS

The third fuzzy system is modelled to obtain a risk value after the impact and likelihood factors for an identified risk assessed and the outputs are generated.

By referencing this graphic, the membership functions for “impact (I)” factor are generated (see Table 12).

The impact value of 6,86 and the likelihood value of 6,38 both coincides with the range of 6

Figure 6. Input parameters membership functions for the risk value

Table 12. Impact membership functions

Condition	Membership Degree	Fuzzy Set
$0 < I \leq 1$	$I_{md} = 1$	Too low
$1 < I < 2$	$I_{md} = 2 - I$ $I_{md} = I - 1$	Too low Low
$2 \leq I \leq 3$	$I_{md} = 1$	Low
$3 < I < 4$	$I_{md} = I - 3$ $I_{md} = 4 - I$	Moderate Low
$4 \leq I \leq 6$	$I_{md} = 1$	Moderate
$6 < I < 7$	$I_{md} = I - 6$ $I_{md} = 7 - I$	High Moderate
$7 \leq I \leq 8$	$I_{md} = 1$	High
$8 < I < 9$	$I_{md} = I - 8$ $I_{md} = 9 - I$	Too high High
$9 \leq I \leq 10$	$I_{md} = 1$	Too high

where “ I ” implies impact, “and “ md ” implies membership degree. The membership functions for likelihood factor is identical with impact factor and was not represented here separately. Below are the if-then rules, which help to make associations between the impact and likelihood inputs and the risk output.

– 7 in the membership degree functions provided. Accordingly:

$$\begin{aligned}
 I_{md} &= (6,86 - 6) = 0,86 \text{ (high) - 86\% “high” set member,} \\
 &= (7 - 6,86) = 0,14 \text{ (moderate) - 14\% “moderate” set member.} \\
 L_{md} &= 6,38 - 6 = 0,38 \text{ (high) - 38\% “high” set member,} \\
 &= 7 - 6,38 = 0,62 \text{ (moderate) - 62\% “moderate” set member.}
 \end{aligned}$$

As both factors (I and L) are members of “2” sets, there appear $2 \times 2 = 4$ rules which are nonzero (see 13, 14, 18 and 19th lines in Table13). The fuzzy rule strength for the example with the nonzero value, calculated through the minimum method, is shown below.

By using the aggregation method of maximum Table 16 is generated.

Table 17 shows the area values calculated for each system output using the values provided above.

As a consequence of the defuzzification process at this stage, the risk score is calculated to be 73,95. The risk score produced by MATLAB stands at 74,5.

Most risk assessment calculations involve the multiplication of the impact and likelihood values. In practice, a risk matrix, which is developed using this calculation, is cited to this end. By classical calculation for the numerical example, we come up with:

- Impact = $(7,5 + 6,4) / 2 = 6,95$
- Likelihood = $(7+6) / 2 = 6,5$
- Risk = 45,175

By this method, the risk value for the relevant process, would be 45. By this point of view, the weight imposed on the risk by the impact and the likelihood is assumed to be the same and the resulting value of 45 would be considered to be a moderate risk. When the risks associated with the all processes and actions are considered, a comparison will reveal sharp distinctions.

Fuzzy logic is considered to be advantageous in particular where the numerical value used to rate the risks as well as the impact and likelihood factors affecting the risks is close to the threshold.

FUTURE RESEARCH DIRECTIONS

Any studies related to a future projection suffers from the vagueness and unforeseen variability. For eliminating these shortcomings, more and more

data acquisition and processing is very critical. The approaches modelling the vague future have to use expert opinion with real and historical data and have to be flexible to be updated rapidly by

new acquisitions. The fuzzy logic based model which provided here should be enriched by new inputs of likelihood and impact factors for operational usage.

Some risk factors like structural changes, previous audit consequences, information technologies usage, social impacts, irregularities and fraud parameters –or any other specific parameters related to market- to be injected in the impact and likelihood FIS will provide significant rise on output quality and accuracy. Risk management is

a continuous and repetitive process and created risk map have to be monitored and optimized periodically. This dynamic process creates the obligation of updating or revising the fuzzy rules according to these possible changes. The algorithm indicated in this study provides a convenient basic for developing a flexible software for creating a risk map. All the processes that an Organization carries out can be listed with their related risk factors to be processed by fuzzy logic based risk assessment algorithm.

For many Organizations, impact may be more important than likelihood in risk assessment. Considering this hypothesis, new fuzzy logic approaches that uses different weights or coefficients for these two factors can be developed. It is also possible to enhance precision by replacing the Mamdani FIS used in this study by Sugeno FIS.

It is predicted that fuzzy logic approach can also be applied to the other aspects of strategic management in addition to risk assessment.

CONCLUSION

Risk assessment is a continuous and recursive process that includes a cost-benefit analysis in order to maximize the use of the opportunities and minimize the threats. All organizations are risk-prone as they function to achieve their objectives. Achievement of the objectives depends on whether the organization is aware of the risks and able to respond accordingly.

Risk assessment plays a significant role in institutional management. In addition to its status as a prominent actor, risk assessment is also dominated by uncertainty. As the subject matter of risk is any event likely to occur in the future, risk-related studies rely heavily on experience, statistical data and prospecting.

Risk, in classical method, is calculated by multiplication of impact and likelihood factors.

This value is classified as low, moderate and high using a 3x3, 5x5 or 10x10 matrices. One of the restrictions of the classical approach is the separation by precise values. For example, in a scale of 1 and 25, a score of 15 indicates a moderate level whereas a score of 16 is considered high.

Fuzzy logic has advantages in the field of risk assessment thanks to its accuracy in modeling uncertainty and feasibility to be modeled in a similar way to human reasoning. Providing a theoretical and exemplary account of the fuzzy logic process, this study aims to provide the foundation of the concept for those interested in the subject.

The algorithm and the fuzzy sets used in this study are expressed as in plain terms as possible for the purposes of clarity and ease of use. A number of studies on fuzzy logic and strategic management have been investigated for the purposes of this study and it has been observed that fuzzy logic is also applicable to different areas of strategic management in addition to risk assessment.

KEY TERMS AND DEFINITIONS

Fuzzy Logic: A field of study which centers on the human reasoning process and operates by converting it into mathematical functions.

Fuzzy Inference System (FIS): The system which is a way of mapping an input space to an output space by using fuzzy set theory. FIS uses a collection of fuzzy membership functions and rules to generate an output.

Risk: The possibility of any event occurring that may stop businesses or companies from

achieving their strategic, financial and operational goals.

Risk Assessment: The process of identifying, evaluating and managing potential events and situations to provide a reasonable level of confidence for the achievement of the business goals.

R

ENDNOTES

- ¹ In general, in risk assessment process, a team consisting related process's responsables and the other related staff rates any certain risks and the average of these points reveals risk score. Thus, risk score is commonly a decimal value. However, especially in traditional matrix method, the decimal values are rounded.
- ² Centroid defuzzification returns the center of area under a curve. This center is calculated by getting the average values of x and y axis of the related shape (triangular and trapezoid in this study). Centroid value is referenced to x axis value of the calculated center's axis.

Predictive Analytics and Intelligent Risk Detection in Healthcare Contexts

Nilmini Wickramasinghe

Epworth HealthCare, Australia & Deakin University, Australia

INTRODUCTION

Healthcare costs globally continue to rise and the US in particular is struggling to contain healthcare costs (Wickramasinghe et al., 2015; 2012). This has led most OECD countries to focus on healthcare reform coupled with greater investment in IS/IT to facilitate superior healthcare delivery (Wickramasinghe et al, 2015). At the same time, the federal government has affected policy to emphasize meaningful use of such technology in healthcare (Wickramasinghe et al., 2015, “Meaningful Use,” 2012). Hence, it is now prudent to develop appropriate technology solutions that not only comply with this requirement but also facilitate superior healthcare delivery to ensue.

An area that can particularly benefit from the application of technology solutions is that of equal experience and trying to provide equality of care and access to all citizens. A key area within healthcare disparities relates to access of language services in healthcare or more specifically supporting limited English proficient patients (LEP patients). In particular, English language proficiency should not impinge on access to- and quality of- service for healthcare. Improving access to language services in healthcare has been an ongoing issue that continues to be at the forefront of various healthcare agendas ((Au et al., 2009; Barrett et al., 2008; Chen et al., 2007).

BACKGROUND

Recent discussions on healthcare disparities (Gibbons, 2011) all note the significant potential benefit technology can make in trying to provide

DOI: 10.4018/978-1-5225-2255-3.ch589

an equal experience to all Americans. Sadly, while there are many good points about the US healthcare system, there also exists a considerable racial and ethnic disparity in the delivery of healthcare across the US (ibid). The underlying root causes for these disparities are all amenable to interventions using IS/IT (information systems/ information technology). The thesis of this paper is that technology is well suited to assist is that of limited English proficiency (LEP).

More than 23 million Americans today have limited English proficiency, which in turn has a negative impact on their ability to receive and comprehend appropriate healthcare delivery (Youdelman, 2008; Flores et al. 2008). Integral to the delivery of care is communication between doctor and patient; however, language barriers typically lead to problems such as delay or denial of services, issues with medication management, and underutilization of preventative services (Green et al, 2005; Jacobs et al, 2004; Ghandi et al, 2000; Karliner et al, 2004). The literature suggests that the quality of communication between Although Title VI of the Civil Rights Act 1964 has always required that entities receiving federal funds provide language services to those with LEP, the law has not often been enforced in healthcare settings (Jacobs et al., 2006). However, awareness of the need to provide language services in healthcare has increased in recent years (Gibbons, 2011).

Current Problem

In 2001 The Institute of Medicine has published two key reports “To err is Human” and “Crossing the Quality Chasm”. Taken together these

reports highlight that patient safety should be one of the essential components of high quality healthcare and that patients should not be harmed by the care that is intended to help them. These profound statements have had far reaching impacts to policy reform and efforts to address patient safety and quality of care delivered today. The role of language barriers and their impact on adverse events is thus now also receiving heightened attention. Especially given that research is consistently highlighting that adverse events affect LEP patients disproportionately more and result in serious consequences to the patient.

Approximately 57 Million people or more than 20 percent of the US population speak a language other than English and this figure is growing while approximately 8.6 percent of the population is defined as LEP. Thus at least 8.6 percent of the US population is at risk for adverse events because of barriers associated with language issues. This adds further cost pressures to an already strained healthcare system

To address this problem a technology mediated solution is proffered to provide multi-lingual support at in-take and registration for LEP patients.

Development of the Conceptual Model

Web 2.0 technology and cloud computing which provides and facilitates anytime anywhere access to (Troshani et al., 2011; Svantesson and Clark, 2010; Mell and Grance, 2010; Gilbert, 2010; Amazon, 2011; Armbrust et al., 2010), affords us the possibility to leverage these technology benefits to design and develop an appropriate solution to address the problem – a portal that support multi language real time translation at intake and registration. Figure 1 provides the conceptual model.

From the above conceptual model in Figure 1, it is possible to model the intake process into critical steps. All these 13 steps of care must be addressed in the technology solution and/or suite of solutions if the solution is to provide the necessary assistance for LEP patients. Taken together these steps traverse the healthcare encounter at intake.

PILOT STUDY

The developed solution was then tested in a small pilot study to assess its reliability and feasibility.

Figure 1. Conceptual model

A 2 arm control study was designed where both English proficient patients and Spanish proficient patients were randomly selected at a leading MidWest Multi-specialty healthcare facility. Before the study commenced appropriate ethical clearances were obtained. Table 1a and b detail the results from the two week pilot trial as well as the activities that were observed in the study.

Results

The study qualitatively measured the interactions between the patients and the electronic kiosk, the value of a clear and concise intake summary for the physician at the beginning of the medical encounter and the ability of the administrative team in the department to take advantage of the completed electronic intake form for other purposes. There was no attempt to integrate the intake form with electronic medical records. Table 2 summarizes the key findings.

FUTURE RESEARCH DIRECTIONS

Two areas are especially critical when considering future developments of the technology mediated solution. Specifically, one area is to assess the health literacy of the patients no matter if they are LEP or proficient English language speakers. The other key direction involves developing and enlarging the languages offered to include Chinese, polish, Farci and German as these are the foreign languages most in prevalent within the US.

CONCLUSION

The US healthcare provider setting is working to deliver the best possible patient care. It must also meet cost of service objectives and provide physicians the best possible tools to meet patient's expectations. Technology in its many applications will continually be employed and adapted to ac-

Table 1a. Study activity

Actor	Before	During Study
Spanish Speaking Patients	Handed an English language intake form and were asked to fill it out to the best of their ability Often had a family member fill out the form, forms were often difficult to read and were incomplete If no family member was present a Spanish speaking staff administrator was taken off their job and asked to serve as interpreter and fill out the form with patient and increased the cost of serving an LEP patient Completed Forms were often difficult to read and of marginal value to physician provider Cultural behaviors limited the ability to gather information, Older Hispanics, men and women are very reluctant to volunteer information Completed form given to administration desk Completed form was placed in patient intake folder and was available to physician, was not available for other purposes Wait times varied as to availability of	Asked to participate in beta study, if agreeable directed to intake kiosk Offered Spanish language form which was translated into English per study description by medically competent interpreter. In some cases family member filled out form in other cases interpreter filled out form. No problems observed in using kiosk technology Form presentation was clear and understandable by patients Completed form given to administration desk Completed form in electronic format was available for other purposes such as Average duration of form completion action was not a factor
English Speaking Patients	Given paper form Filled out form to best of ability Very often completed forms were not easy to read and of minimal value to physician Completed form was placed in patient intake folder and available to physician, was not available for other purposes	Given option of using electronic intake kiosk with drop down menus and input boxes Faster intake form completion Intake form presentation was clear and understandable by patient Completed form was placed in patient intake folder and available to physician and available for other purposes
Physician	Clarity of intake form depended on writing and communication skill of patient	Electronic format provided easy to read and use intake form
Administration	Begins w patient request for appoint and scheduling of appointment, and request for completion of paper forms prior to actual appoint, on appointment date Patients rarely completed intake forms in advance of appointment If patient did not complete intake form prior to visit a blank form was presented to patient at time of visit If patient was a Spanish speaker a family member or staff would assist with intake completion If no family member available administration staff acted as interpreter. Completed form was used presented to administrator	Administration asked English or Spanish speaking patients if they would be interested in completing an intake form electronically and in native language. Once form was complete either handwritten or electronic it was returned to the administration and placed in the intake folder for clinical visit with physician.

Table 1b. Control – English speaking patients

Actor	Event	Outcome
English Speaking Patient	English speaking patients are offered option of traditional paper intake form or completing the form at kiosk with touch screen and drop down menu capabilities.	The Department of Urology serves an aged skewed population. As a general rule the younger the patient the more likely they were to opt for the electronic format. 80% of the patients offered the electronic option chose for to use that. Several patients commented that the electronic version was much faster to use and more consistent with a modern healthcare setting. Other inquired if the electronic form was transferable to other departments. For those patients that chose the electronic version patient satisfaction ranged on the scale of 4 or 5 with 5 being the highest on a 1 to 5 scale.
Spanish Speaking Patient	Spanish speaking patients are offered option of the traditional paper intake form or completing the form at kiosk with touch screen and drop down menu capabilities. The hand written intake form provided by the administration was not translated into Spanish, consequently each Spanish speaking patient opted for the electronic version of the form offered in their native language.	In each case at the electronic kiosk, translator services were incorporated to facilitate the completion of the intake form. Spanish speaking patients were afforded the opportunity to complete the intake in their language while the administration and physician were provided an English language version of the intake form. In each case customer satisfaction was rated a 5 on a 1 to 5 scale. Multiple copies of the completed intake form given to each patient for potential use in other departments.
Physician and Patient	English and Spanish speaking patients were queued to meet with the physician in a business as usual manner.	Physicians who had access to the electronic forms regardless of language spoken by the patient rated the clarity of the information on the electronic form higher than the hand written form. Also, physicians stated that the quantity of the information was greater and offered a more clear picture of the patient medical, family and social status. Physician satisfaction with the electronic form over the handwritten form was ranked higher because the electronic form was easier and faster to read. See appendix xx for sample of handwritten and electronic form.
Administration and Patient	Once the intake forms were completed (English and Spanish), they were handed to the front desk for administration, placed in the patient intake folder and placed in queue for the physician. The form is reviewed by the physician. It is generally not used beyond physician review for other purposes.	After the physician encounter patients were often asked to complete other forms very similar in content to the original intake form. Form redundancy is a major detractor to patient satisfaction and high cost component to administrative efficiency. No other forms have a language assistance component. The impact of this is obvious i.e. when a dietary requirement is needed before a test can be conducted and this requirement is not met on the day of the scheduled procedure because the instructions were not understandable by the non-English speaking patient.

Table 2. Summary of findings

Actor	Event	Outcome
English Speaking Patient	English speaking patients are offered option of traditional paper intake form or completing the form at kiosk with touch screen and drop down menu capabilities.	The Department of Urology serves an aged skewed population. As a general rule the younger the patient the more likely they were to opt for the electronic format. 80% of the patients offered the electronic option chose for to use that. In each case at the electronic kiosk, translator services were incorporated to facilitate the completion of the intake form. Spanish speaking patients were afforded the opportunity to complete the intake in their language while the administration and physician were provided an English language version of the intake form. In each case customer satisfaction was rated a 5 on a 1 to 5 scale. Multiple copies of the completed intake form given to each patient for potential use in other departments.
Physician and Patient	English and Spanish speaking patients were queued to meet with the physician in a business as usual manner.	Physicians who had access to the electronic forms regardless of language spoken by the patient rated the clarity of the information on the electronic form higher than the hand written form. Also, physicians stated that the quantity of the information was greater and offered a more clear picture of the patient medical, family and social status. Physician satisfaction with the electronic form over the handwritten form was ranked higher because the electronic form was easier and faster to read. See appendix xx for sample of handwritten and electronic form.
Administration and Patient	Once the intake forms were completed (English and Spanish), they were handed to the front desk for administration, placed in the patient intake folder and placed in queue for the physician. The form is reviewed by the physician. It is generally not used beyond physician review for other purposes.	After the physician encounter patients were often asked to complete other forms very similar in content to the original intake form. Form redundancy is a major detractor to patient satisfaction and high cost component to administrative efficiency. No other forms have a language assistance component. The impact of this is obvious i.e. when a dietary requirements is needed before a test can be conducted and this requirement is not met on the day of the scheduled procedure because the instructions were not understandable by the non-English speaking patient.

comply with these goals. Technology that facilitates communication between the patient and the provider (physician and administration) will have an important role. All healthcare interactions begin and end with communication between the provider and patient. This is a determining factor in successful health outcomes. With greater clarity and availability of patient information there is a greater probability of meeting patient need and managing the cost of delivering service. For example, it is well documented that language barriers (communication barriers) between patients and providers are a leading cause of healthcare disparities. Communication barriers are not limited to the interactions between the patient and physician but also include the patient's interactions with the physician supporting healthcare infrastructure.

Communication Barriers Impact

Patient: Physician communication, for example,

1. The inability for physicians to understand a patient's need and thus increase the potential for medical errors and the associated higher cost of service.
2. Poor communications between the physician and patient extends the healthcare encounter and creates delays in physician access.

Patient: Administration communication, for example,

1. The ability for the patient to follow with procedural or pharmacy instructions,
2. The ability for patients to provide or understand billing or insurance information and
3. the ability to follow up with next steps in a treatment protocol which leads to higher cost of service.

This study represents a first step to understand the impact of using an electronic intake format for gathering patient information from both English speaking and non-English speaking (LEP) patients. Healthcare disparities plague the US healthcare system and language proficiency is one of these key barriers. Technology does have the potential to reduce this barrier effectively and

efficiently so that superior care delivery might ensue. The proffered solution described in the preceding holds the key to potentially addressing this challenge.

KEY TERMS AND DEFINITIONS

Cloud-Based Computing (or Cloud Computing): When computing resources such as software and hardware are delivered as a service over a network.

Healthcare Delivery: The network, structure and stakeholders involved in administering medical care to individuals.

Human Interpreter: Person who performs language translation.

Language Translation: The act of converting the meaning into a different language.

LEP-Limited English Proficiency: Individuals for whom English is not their native language and thus have difficulty communicating and understanding in English.

Meaningful Use: Federal government stipulation for technology solutions in healthcare.

Real-Time Translation: Translation that happens instantaneously at the point of action.

Stress Testing Corporations and Municipalities and Supply Chains

R

Frank Wolf
CSSTA L3C, USA

INTRODUCTION

Assuring the likelihood of survival is the fundamental reason for stress testing large banks in Europe and the United States under the mandates called Basel I, II and III, and CCAR respectively. Similarly stress testing corporations, not-for-profit organizations, and municipalities, has become a necessary exercise to prevent insolvency in times of economic uncertainty and shortened corporate life expectancy.

The concept of stress testing is not entirely new. For example, computer software gets routinely stress tested in order to assure it can survive volume fluctuations, data storage requirements and hacking attempts. In the field of engineering, stress testing materials under conditions of extreme heat, cold, or loads has been around for ages. In the banking sector of our economy stress testing means having sufficient capital to meet current obligations and even prevent runs on your neighborhood ATM. So the logical extension of this reasonable practice is to stress test mid-sized or large firms, non-profits and municipalities with respect to solvency, with the intent to preserve public services, commercial products, peoples' jobs, invested capital, supplier and customer relationships and quite possibly preserve whole communities!

It is very well established in the academic and business literature that both insolvency and bankruptcy are predictable phenomena for the vast majority of cases.² However, testing for those conditions is not yet customary for businesses and municipalities. During the 1960s managers

presumed that a certain percentage of business failures were to be expected and that these constituted the risk of market entry. More recently the Harvard Business Review⁹, dedicating an entire issue to business failure, postulating that *not* succeeding constitutes a learning experience which one should embrace and not be ashamed of. The clear message is this: learn from your failure and then try again, only do better next time. That is acceptable in theory, just don't tell this to a failing entrepreneur with a great idea who has just mortgaged his house and put his entire future at risk. Failure is not a good thing and many types of failures are both predictable and most importantly preventable. The fiduciary responsibility for preventing business insolvency rests primarily with directors and corporate officers, individually and collectively. States are on the line for municipal failures under Chapter 9 of the U.S. Bankruptcy Code irrespective of whether Chapter 9 applies. States do bear a large reputational risk as future borrowing costs may increase.

BACKGROUND

Legal Considerations for Stress Testing Corporate Entities for Insolvency Risk

Insolvency

Bankruptcy is a legal system set up by the U.S. Congress to administer insolvency of individuals or corporations. That should not be mistaken for

business insolvency which is commonly described as the financial distress caused when either or both:

1. An entity's debts exceed the assets it owns ("balance sheet insolvency"); or
2. When the party does not have the cash, or liquidity, to meet its payments as they become due ("cash flow insolvency").

There are other ways outside the bankruptcy system to attempt to resolve insolvency. Although the code offers many advantages to an entity in financial distress, it could be in the best interest of the company to avoid the formal bankruptcy process, and instead attempt to reorganize outside the federal court system.

The bankruptcy process is extremely costly, kicks in too late, and is time consuming and frustrating to debtors and creditors alike, as the process returns very little to creditors that are unsecured or even to those with priority treatment.

The low plan confirmation and low plan completion rates, and the high conversion and high dismissal ratios, indicates that early detection of insolvency risk would be hugely beneficial. The implementation of effective and efficient preventive measures should be emphasized and promoted, if not required, as part of good corporate governance. In other words, corporate stress testing may soon become a mandate for public corporations!

By implementing a program that helps to identify early-on the risk of insolvency, a company may avoid the many uncontrollable pitfalls that could occur with a late bankruptcy Chapter 11 reorganization filing.

Once a business is within a judicial bankruptcy process, it may lose control of the possibility of dismissing the petition even though it was voluntarily filed, and instead face a forced conversion and a liquidation scenario with a possible hostile trustee and disgruntled creditors.

Statistics show that the advantages of a bankruptcy filing include:

1. The automatic stay of most, but not all, litigations and
2. The possibility of removing or discharging some unsecured debt.

Finally the system can be "gamed" in terms of favoring the secured and some other preferred parties to the detriment of the unsecured and even priority creditors, who receive on the average, a very small distributions from the estate assets.

For example, in chapter 7 liquidations, according to the official court data for calendar year 2008, and based on the 63,000 Chapter 7 cases with assets, closed in that period with over \$2.6 billion in receipts, secured creditors received 28.9% of total amounts distributed; priority creditors received 4.4%; unsecured creditors 25%; and debtors and third parties 8% for a total distribution of \$1.785B or 66.2%. At the same time the total fees paid out to the professionals in these asset cases, mostly legal, trustee fees and administrative charges were 33.8% of the total distributions made. (Haverstock and Crewson, 2012)

However, these figures do not consider that in no-asset cases, which are nearly 97% of all Chapter 7 matters, unsecured creditors receive almost no distribution.

The legal considerations notwithstanding, statistics often quoted (Reeves¹) find that today's public companies have a 1:3 chance of disappearing within five years due to a combination of bankruptcies, liquidation, delisting, mergers and acquisitions. That disappearance rate is 6 times larger than it was 40 years ago and calls for a governance model (Reeves²) of planning for multiple time scales in which stress testing is a good start.

Corporations

The U.S. Bankruptcy Code provides corporations with various reorganization options that must be considered in today's complicated business environment. These options may include corporate

reorganization, recapitalization or sale of substantially all or some assets, and possibly liquidation of an entire business. However, it also entails hidden pitfalls that may outweigh its benefits.

Whether one chooses a straight Chapter 7 liquidation process, or reorganization under Chapters 11 or 13, private businesses that approach the nebulous zone of insolvency, or that are at risk of falling into such an area, must consider the various scenarios available to avoid getting caught in what could be a precarious bankruptcy judicial process.

Also, prepackaged reorganizations, or out of court debtor-creditor arrangements that avoid the time and cost of the judicial code administration, must be understood and considered.

The complexity arising from options the Code provides to individuals, corporations and partnerships facing business failure is enormous, and requires a great deal of expertise and time to sort out. Not only is research and planning involved in the pre-bankruptcy stage, but also complying with the filing requirements and the regulatory provisions under the joint judicial-administrative procedures of Chapter 11. The task is daunting, even for a firm that can afford the time and expense involved in advanced planning and compliance. (UCLA-Lopucki, 2012)¹⁴.

Although “success” in terms of a Chapter 11 bankruptcy case is difficult to define, it has been measured by the time taken to complete a case, to get the plan of reorganization confirmed, whether the company eventually emerges as a stand-alone company, or if the debtor had to re-file after a short period of time.

These measurements will vary according to the type of bankruptcy and chapter selected to be filed. Also, many so called “reorganizations” actually constitute business liquidations and involve a sale of most or substantially all the assets of the company under the Chapter 11 judicial reorganization umbrella.

Such measurements do not necessarily indicate the degree of failure or success of a case that has

been converted to Chapter 7 liquidation, or dismissed by the court for cause, and whose assets, employees and clients get reintroduced somehow into the economy and become productive parts outside the judicial bankruptcy system.

The federal bankruptcy courts received, during the 12 months period ending in March 2012, a total of 1,367, 006 new filings, of which only 46,393 constituted business filings for which corporate stress testing may have been beneficial. That is, cases in which the debtor is a corporation, partnership, or if the debt is primarily related to a business of some kind belonging to this category. This in contrast to consumer-individual cases (non-business) in which debt was incurred primarily for personal family or household purposes. (Administrative Offices of the U.S. Courts, 2012).¹ The number of Chapter 11 cases stood at only 11,339, but of these only 9,616 constituted business filings and 1,723 were non-business debt related.

In terms of comparing different outcomes and success rates between the various bankruptcy code filing options, the numbers show that only a third of the Chapter 11 cases are ever confirmed or approved by the court; that 22% are converted to Chapter 7 liquidation; and that over 35% are dismissed. That is, they never get to the confirmation stage and instead are resolved somehow outside the judicial bankruptcy system.

After the 2005 amendments to the U.S. Code, the average disposition time of confirmation for all Chapter 11 cases filed still exceeds twelve months from date of filing of the petition, and the majority of the cases get converted to Chapter 7 liquidation in nine months and / or dismissed in over seven months. (Flynn and Crewson, 2012)

These official statistics show, that Chapter 11 reorganizations cases filed are rising moderately, the rates are not entirely uniform among the different chapters, they vary among the different states and geographical areas of the nation, and that a very low percentile of cases get to the ideal approval stage of judicial confirmation of a plan

of reorganization. Moreover, about 55% never get confirmed and instead are dismissed or converted to a forced liquidation chapter of the Code.

It is reasonable to infer from these statistics that the financial carnage from business failures is widespread with lasting effects beyond its epicenter. Given an increased fragility in the business environment, preventing the disastrous effects of corporate failures through a well- documented predictive stress testing methodology is called for.

Municipalities

As banner headlines now routinely announce, nations can and do become insolvent, recent examples being Russia, Mexico, Greece, Spain, Ireland and others. Failed US cities include Detroit MI, Hillview KY, San Bernadine CA, Stockton CA, Jefferson City AL, Central Falls RI, and Boise City ID, among others. Since nations cannot be dissolved, the sovereign settlement mechanism that has evolved post WWII is called the Paris Club. U.S. States, with the exception of Vermont, are state- constitutionally bound to balance their budgets. But that usually only applies to the General Funds accounts, into which most tax income flows and from which operational expenses are paid. Many other forms of commitments are not included, and therein is the problem of pending insolvency of municipalities.

Municipalities may qualify under the U.S. Bankruptcy Code Chapter 9, where Vermont and 24 other States are again the exception. For those exceptions, the respective legislature must enable Chapter 9 for a designated town. The Chapter 9 rules are slightly different for a municipality, for example:

1. A town cannot involuntarily be put into Chapter 9 as it only applies to public agencies or instrumentalities of the state.
2. Judges in these matters are assigned by the chief judge of the circuit rather than the clerk.
3. The debtor bears the burden of proving insolvency.

4. Actions against the municipality or its individuals are automatically stayed.
5. Collective bargaining agreements can be modified under the rules, but not unilaterally abrogated, etc.

The net effect in all those Chapter 9 cases sadly is always the same. Once filed, money ceases to flow and can't be raised for new projects, economic activity leaves town, and only few investment can be made. Clearly an undesirable conditions similar to commercial insolvency, which does not happen overnight and which can be predicted, and in many cases steps can be taken to prevent total collapse.

THE CASE FOR STRESS TESTING CORPORATE ENTITIES, INCLUDING NON-PROFITS AND SUPPLY CHAINS

The process of stress testing corporations differs from that of stress testing banks which is governed by Basel I, II, and III rules (EU) and CCAR (US). The difference is that bank stress testing is mandated by governmental regulators worldwide, while in the corporate world stress testing is only advisable. To begin with, the stress testing process, if done well, is organization specific and includes a quantitative analysis based on current conditions, followed by running future scenario models, which are both quantitative and qualitative. A reasonable approach is to first conduct a ratio analysis, as follows:

1. For the target enterprise collecting financial operating data about a company and its major competitors for three to five prior years is essential. Sources are quarterly or year-end balance sheets and operating statements. The next step involves computing of ratios such as the solvency ratio, quick ratio, current ratio, and several more as may be appropriate for a specific case under review. Doing the same for all competitors establishes a basis for comparisons, a benchmark or standard.

2. Insolvency and bankruptcy for most cases are predictable². Producing graphical output of ratios over time often establishes a trend line and some insight into the client, their competitors and the industry averages.
3. Compute the Altman Z-Score², which is a multivariate regression formula of financial ratios that correctly predicts bankruptcy two years out between 70% and 80% of the time. The value Z is a number meaning standard deviations above or below the mean.
4. Risk scenario: This stage in the analyses needs to be reviewed with corporate management in order to chart a path for developing alternative and plausible scenarios.
5. Scenarios are likely future events that could lead to financial distress and eventual business failure. The importance of correctly structuring and modeling these scenarios cannot be overemphasized, as they can provide actionable insights to predicting failure and to its prevention.

Scenario development involves the following steps: (Schoemaker, 1995)¹⁸

1. Scope, dealing with time frame, market and geography
2. Identification of stake holders and their interests, suppliers, clients, employees
3. Identification of trends, economic, scientific, and political as appropriate
4. Identification of uncertainties, management, elections, interest rates, liquidity
5. The initial scenario should focus on positives and all negatives to build clusters and develop themes, to assess the level of preparedness by management for an uncertain future.
6. Plausibility check, look for inconsistencies and lack of a compelling story.
7. Identify research needs to tackle unknowns, such as effects of cloud computing or destructive new technologies
8. Iteratively evolve into defining decision final risk scenarios to be modeled.

Additional risk factors bearing on the solvency also have to be quantified, including:

- Pending law suits as a claimant or as a respondent during the last 3-5 years?
- Discontinued operations during the last 3-5 years, or plans for future discontinuation.
- Write-offs or impairments during the last 3-5 years?
- Debt defaults during the last 3-5 years?
- Having sought financial partners, disposed of operations, last 3-5 years?
- Is a management succession plan in force?
- Internal control issues, accounting, fraud history?
- Technology issues, obsolescence, creative destruction, electronic hacking risk?
- Competition issues, strength-weakness-threats-opportunities,
- Distribution of clients, Pareto problem, 80%/20%?
- Regulatory issues regarding safety, human resources, environment, sustainability
- Supply chain disruptions as a function of world events, partner insolvency, force- majeure?
- Liquidity, credit and market risks
- Globally changing trade compliance due to international trade agreements or WTO decisions
- Demand volatility, increasing or decreasing, social media.
- Talent management and leadership development to accommodate new technologies
- Transportation network design, trip optimization model opportunities for productivity gain, production bottle necks
- Working capital adequacy to meet corporate growth plans in the near future, including that of supply chain partners, orderly retrenchment.
- Interest rates' effect on finance, Forex
- Inflation effect on performance

Given likely future environments and probable internal risk factors, a simulation model is built in order to answer the “what if” questions that can help management prevent insolvency. Corporate officers and especially Board members have fiduciary responsibilities to shareholders when solvent. When insolvent however, Board responsibility extends to all stakeholders and especially creditors. Hence Board members must be the drivers to institute stress testing in companies to meet their fiduciary duties and to protect themselves from possible legal action.

THE CASE FOR STRESS TESTING MUNICIPALITIES

The object of stress testing municipalities is very similar to that of stress testing corporations, namely to prevent insolvency and bankruptcy under possible stressful future conditions. The difference between corporate and municipal stress testing is in the measurements and the nature of the organization. For one thing, municipalities cannot be dissolved in a bankruptcy process because people still live and work in those locations. There are also differences in the data and organization; municipalities are entities for public service and have a fiduciary responsibility towards tax paying citizens vs. corporations having responsibility to dividend expecting shareholders among others. The final obvious difference is that municipal managers are often elected on issues other than managerial and financial skills, while corporate managers are appointed often on the basis of financial performance and business acumen.

Philosophically the process is similar to that of corporate stress testing, namely collecting data, running statistical analyses and simulating future plausible scenarios. However, there are significant differences between corporate and municipal stress testing approaches. One approach is to consider stress testing state/province-wide and all its municipalities within. Demographic data

is readily available from the U.S. Census, such as town population, income- and age distributions. Each town will most likely have a budget and an annual audit for the current year, all of which would under normal circumstances be publicly available. Consistency of definition of variables from one town to another has to be painstakingly established.

Establishment of a state-wide database combining demographic Census data with municipal financial data is the first step. Classifying towns as either urban, urban ring, rural or suburban offers more chances of segmentation later on. The next step is to develop fiscal stress indicators based on (a) town financial position, (b) town financial flexibility and (c) town tax capacity. An overall index will segment each town in a State into 1-5 rating insolvency risk levels, with 5 being the financially weakest and therefore subject to simulated stress scenarios. Suggested actual measurements for categories (a), (b) and (c) are the following: (Rhode Island, 2011)¹⁷

Financial Position:

- General fund balance at end of fiscal year, dollars
- Quick ratio, which is (total cash and investments)/(notes, loans and liabilities)
- Unfunded pension liability, dollars and percent of budget, per capita
- Annual required contribution to pension funds, dollars

Financial Flexibility:

- State aid, dollars and percent of budget
- Education state aid, dollars per student
- Total property tax revenue, dollars and percent of budget
- Growth in services, dollars
- Debt/revenue ratio
- Employment total benefit payments

Tax Capacity:

- Real estate tax rate
- Per capita tax of owner occupied residential real estate
- Per capita tax of owner occupied commercial real estate
- Median family income

Sponsorship of such studies lies with the States themselves, as they are first in line for assistance. Municipalities have a self-interest in conducting stress tests by an independent outside consultant.

The end result is in the prevention of another Detroit or Puerto Rico.

A CORPORATE STRESS TEST STUDY EXAMPLE

The following is an abbreviated case study from 2012, performed by Corporate Solvency Stress Testing L3C.

The client firm under review is a 75 year old family owned enterprise in the business of transporting freight and packages for supply chains, mostly by truck. It operates in the North Eastern States of the US and has annual revenue below \$100 million. Company assets consist of a large fleet of owned trucks that are mostly ten years or older which in some cases have over 4 million miles on their odometers. Other assets are a network of leased terminals, fully equipped repair facilities and the usual office equipment, plus company fuel pumps at each terminal. Triggered by stress in loan repayment and subsequent deteriorating banking relationship, personnel issues, an auditors' going concern statement, rivalry among two generations of family members working at the firm, a consultant was engaged to resolve the short term stress.

Problem

Multiple small problems can blur the vision to see the big picture. Solving a number of short

term crises may restore tranquility temporarily, however, the root causes of the problem must eventually be solved to assure long term growth and stability. The larger problem in this case was to reduce debt and put the enterprise on a more stable operational platform. The restructuring consultant quickly embarked on several employee terminations and replacement hires for critical financial management positions. In addition, a new banking relationship was established resulting in calming of corporate management, who then agreed to undertake a corporate stress testing regimen. The primary goal of the stress testing process was to assess the firms' survivability under plausible adverse conditions. The time frame to complete this assignment was approximately three months and included the following steps:

1. A three prior year financial ratio analysis based on easily available balance sheets and operating statements.
2. A similar financial analysis of the three largest competitors. These data came from publically available balance sheets and operating statements.
3. A side-by-side comparison of those four firms over the last three years with respect to financial ratios.
4. Developing and running a bankruptcy prediction model for client and competitors and a side by side comparison of all.
5. An interim presentation to management was scheduled, and from it evolved a number of plausible scenarios for the next three years. These quantitative scenarios addressed a combination of cost issues like (a) fuel cost, (b) interest rates, (c) maintenance (d) fuel surcharge, plus current year optimistic and pessimistic budget assumption. Qualitative issues were researched and discussed including competitor behavior changes, fleet replacement buy vs. lease, shipping trends and market share, network optimization, and potential benefits from new logistics technology.

6. Three scenarios were modeled, based on the current budget, and cash flow projections. Monte Carlo simulation gave indicators for future outcomes.

Scenarios

The first dealt with the possibility that fuel costs increase 20% with the market only being able to absorb 40% of that. In another scenario fuel prices, interest rates and maintenance costs, were simultaneously changed from current budget value. In the last scenarios, fuel surcharges were eliminated.

In the Monte Carlo simulation, revenues and fuel surcharges were subjected to sampling from normal distributions to produce a total revenue estimate. Fuel, maintenance and fixed expenses were sampled from their respective normal distribution and combined with the revenue and depreciation to produce cash flow estimates for the current fiscal year. The simulation was run for 255 working days and aggregated to show yearly levels.

Results

The client was deemed marginally solvent based on the solvency related ratio and the bankruptcy prediction model Z-score. However, the client's current ratio was below the industry average giving it a relatively low credit rating of BB. For each of the six runs net profit estimations were generated from which the narrow line between profitability, and or loss became painfully apparent. For the Monte Carlo simulation the measurement was EBITA. The results show that efforts of the short term fix is no fix. While short term fixes were necessary, they offer only momentary reprieve and that continuous monitoring is required. The client will need to formulate a longer term strategy to assure long term stability and hopefully achieve moderate growth. Beyond the strategy to get out of debt over a period of time, there will be many projects that need to be professionally managed. These projects involve the evaluation of the cur-

rent network of terminals, fleet replacement and its effect on maintenance and operations cost, etc.

The final step was an Opinion Letter to the Board, in which case the firm was found to be solvent for now, which means that its immediate ability to pay current obligations appeared secure. Long term profitability, however, could only be secured with the Board making a combination of simultaneous expansion and contraction decisions to establish a new growth path. Stress Test related Opinion Letters by third parties are neither accounting nor legal documents but are helpful in showing good faith and governance.

Having gone through this process, the Board was able show good governance practices should the company become insolvent sometime in future. A future bankruptcy court would be less likely to reverse past management decisions made while the company was certifiably solvent.

FUTURE RESEARCH DIRECTION RELATIVE TO INSOLVENCY RISK MANAGEMENT

While stress testing corporations and municipalities for solvency is relatively new, research to establish good measurements and processes will need to be developed in order for this preventive medicine to affect society. Not only is there a burning need to refine the process and make corporate and municipal stress testing as routine as seeing a dentist every six months, there is also a need to understand the forces that resist stress testing efforts, namely the notion that ignorance is bliss. In the corporate market, those forces operate mostly in mature organizations with an ingrained management team. For municipalities those forces are elected managers without management skills.

For corporations and non-profits, there is a pressing need to standardize the process of corporate stress testing and find appropriate measurements. Third party advisors in cooperation with trade associations are suitable entities to undertake such projects. Public accountants

and bankruptcy law firms are too close to their clients to be neutral, and certainly can't write a "Letter of Solvency" likely to stand up in court.

For Board members the responsibility is clear. Their personal liability is such that if knowingly or unknowingly insolvent, their responsibility widens to include creditors, customers and other stakeholders, rather than just shareholders.

With municipal failures on the rise, possibly in Puerto Rico, there is a danger that Chapter 9 bankruptcy will increasingly become a strategy for fiscal relief, just as Chapter 11 became strategy for airlines at one time not too long ago. While a model processes for stress testing municipalities exist for New York State for example, the research goal should be to simplify the process and standardize the measurements so that the municipal stress testing can be done by the municipalities themselves. In the interim, third party stress test advisors are appropriate sources to tailor the process to geographic uniqueness. These models and methods should become part and parcel of the municipal budgeting process with special emphasis on the capture of off-book commitments.

For corporate supply chain partners it is obvious that financial weakness of one member affects all. It is clear that more work needs to be done to assess supply chain solvency risk as well as those risks that fall under the category of force-majeure.

The technology is rapidly approaching the state in which a *software agent* will be able to continuously do the mechanical stress testing activities for a single firm, supply chain, or municipality. In particular to capture the balances on key financial statements, compute financial ratios relative to debt, assets, cash flow etc., to compare those with comparable enterprises from public data bases, and create a management dashboard of solvency risk change. While risk scenarios are unique to each enterprise, even a data bank of scenarios can be defined and stored for semi-automatic Monte Carlo simulations with defined parameters to answer *what-if* questions. The end result and ultimate objective of permanent stress testing can and should be automated and become part of perpetual good governance.

CONCLUSION

The field of corporate and municipal solvency stress testing is an evolving technology with strong implication for a social good. The social good in cases of both corporate and municipal insolvencies is in the preservation of jobs, beneficial use of technology and strengthening services to communities, fostering viable investments and avoiding enormous waste due to preventable insolvencies and bankruptcies. The social good is also in leading to managerial preparedness to face rapid changes in the economic environment head on, in other words, good governance. But, it is hard to convince managers to be prepared for events that may not occur; until they do occur.

In this paper, the authors established the following:

1. A state of insolvency in both corporations and municipalities can be defined, and that insolvencies are a leading indicator for bankruptcy, which is statistically predictable.
2. A meaningful recovery of value from formal bankruptcy is unlikely, as the process kicks in too late and is too costly; leading to the conclusion that preventive mechanisms in the form of corporate and municipal stress testing are needed.
3. Stress testing processes for corporations, whole supply chains, and municipalities differ from each other with respect to applicable measurements and other parameters.
4. The ultimate vision is for stress testing processes to become part of a predictive analytics repertoire for both corporations supply chains and municipalities. Such processes must be easy to use and understand at the citizen level.

In this paper, the authors have presented an interdisciplinary approach to the process and the measurements for corporate and municipal fiscal stress testing. In addition, the authors presented a case for the advisability to undertake such actions sooner rather than later in light of continuing uncertainty.

KEY TERMS AND DEFINITIONS

Bankruptcy: A successful legal procedure and declaration for seeking protection from creditors. All bankrupt debtors are in fact insolvent. (bankrupt24.co.za, 2012), includes corporations and municipalities. (Jones, Hilbers, Slack, 2004).

Chapter 7: Of the U.S. Bankruptcy code pertains to corporate cases, or individual insolvencies, for which restructuring is unlikely to have success and liquidation the is only option.

Chapter 9: Of the U.S. Bankruptcy code pertains to municipalities, and its applicability varies by State. For example, it does not apply to the Commonwealth of Puerto Rico and is creating challenging legal issues in the 2016 financial crisis there.

Chapter 11: Of the U.S. Bankruptcy code pertains to corporate and personal cases for which reorganization or restructuring is a viable option.

Insolvency: Is defined as the financial state of a person or company or municipality unable to meet its obligations when due. Usually liabilities exceed current assets in those situations.

Scenario: Is a plausible future state of an enterprise or town may find itself in, and it is usually

quite different than what is expected under normal operating conditions.

Stress Testing: Corporations or municipalities for solvency, is a quantitative and qualitative process of showing the likelihood of an organizations' fiscal survival probability under adverse conditions. It addresses the "what-if" question and leads to better decisions, good governance and reduces likelihood of financial stress.

Binary Decision Diagram Reliability for Multiple Robot Complex System

INTRODUCTION

Generally, complex systems in reliability are defined as a system having a combination of series, parallel, R out of N and standby components. Each of these models has the corresponding mathematical formulations for reliability computations leading to decompose the original system (or sub-system) into an equivalent one with a known cumulative distribution function (CDF) or reliability function. Continuing the decomposition procedure enables the decision maker to reduce the whole system to a unique component with a known CDF. For better understanding, an illustrative example for a complex system reduction is given in Figure 1. The system is composed of both series and parallel components which are reduced first to a series system and eventually to a one-component system.

It should be noted that the reduction methods explained before are not effective for all systems. In cases with complicated interrelations of components it is required to develop an efficient methodology. This methodology deals with subjects such as event trees, Boolean representations, coherent structures, cut sets and decompositions.

Network reliability analysis receives considerable attention for the design, validation, and maintenance of many real world systems, such as production, computer, communication, or power networks. The components of a network are subject to random failures, as more and more

enterprises become dependent upon network or networked computing applications. Failure of a single component may directly affect the functioning of a network. So the failure probability of each component is a crucial consideration while considering the reliability of a network. There are so many exact methods for computation of network reliability (Bobbio et al., 2006). The network model is a directed stochastic graph $G=(V, E)$, where V is the vertex set, and E is the set of directed edges. An incidence relation associates with each edge of G a pair of nodes of G , called its end vertices. The edges represent components that can fail with known probability. In real problems, these probabilities are usually computed from statistical data. The problem related with connection function is NP-hard. The same thing is observed for planar graphs (Provan, 1986).

BACKGROUND

The word *reliability* can be traced back to 1816, by poet Coleridge before World War II the name has been linked mostly to repeatability (Saleh and Marais, 2006). A test (in any type of science) was considered reliable if the same results would be obtained repeatedly. In the 1920s product improvement through the use of statistical process control was promoted by Dr. Walter A. Shewart at Bell Labs. Around this time Wallodi Weibull was working on statistical models for fatigue. The

development of reliability engineering was here on a parallel path with quality (Juran and Gryna, 1988). The modern use of the word *reliability* was defined by the U.S. military in the 1940s and evolved to the present. It initially came to mean that a product would operate when expected (nowadays called “mission readiness”) and for a specified period of time. In the time around the WWII and later, many reliability issues were due to inherent unreliability of electronics and to fatigue issues. In 1945, M.A. Miner published the seminal paper titled “Cumulative Damage in Fatigue” in an ASME journal. A main application for reliability engineering in the military was for the vacuum tube as used in radar systems and other electronics, for which reliability has proved to be very problematic and costly. The IEEE formed the Reliability Society in 1948. In 1950, on the military side, a group called the Advisory Group on the Reliability of Electronic Equipment,

AGREE, was born. This group recommended the following 3 main ways of working:

- Improve Component Reliability;
- Establish quality and reliability requirements (also) for suppliers;
- Collect field data and find root causes of failures.

In the 1960s more emphasis was given to reliability testing on component and system level. The famous military standard 781 was created at that time. Around this period also the much-used (and also much-debated) military handbook 217 was published by Radio Corporation of America (RCA) and was used for the prediction of failure rates of components. The emphasis on component reliability and empirical research (e.g. Mil Std 217) alone slowly decreases. More pragmatic approaches, as used in the consumer industries,

Figure 1. A complex system reliability

are being used. The 1980s was a decade of great changes. Televisions had become all semiconductor. Automobiles rapidly increased their use of semiconductors with a variety of microcomputers under the hood and in the dash. Large air conditioning systems developed electronic controllers, as had microwave ovens and a variety of other appliances. Communications systems began to adopt electronics to replace older mechanical switching systems. Bellcore issued the first consumer prediction methodology for telecommunications, and SAE developed a similar document SAE870050 for automotive applications. The nature of predictions evolved during the decade, and it became apparent that die complexity was not the only factor that determined failure rates for Integrated Circuits (ICs). Kam Wong published a paper questioning the bathtub curve (Wong, 1981; see also O'Connor, 2002). During this decade, the failure rate of many components dropped by a factor of 10. Software became important to the reliability of systems. By the 1990s, the pace of IC development was picking up. Wider use of stand-alone microcomputers was common, and the PC market helped keep IC densities following Moore's Law and doubling about every 18 months. Reliability Engineering now was more changing towards understanding the physics of failure. Failure rates for components kept on dropping, but system-level issues became more prominent. Product development time continued to shorten through this decade and what had been done in three years was being done in 18 months. This meant that reliability tools and tasks must be more closely tied to the development process itself. In many ways, reliability became part of everyday life and consumer expectations.

Complex systems are characterized by large numbers of components, cut sets or link sets, or by statistical dependence between the component states. These measures of complexity render the computation of system reliability a challenging

task. Der Kiureghian and Song (2008) developed a decomposition approach which, together with a linear programming formulation, allows determination of bounds on the reliability of complex systems with manageable computational effort. The approach also facilitated multi-scale modeling and analysis of a system, whereby varying degrees of detail can be considered in the decomposed system.

In problems of maintenance optimization, it is convenient to assume that repairs are equivalent to replacements and those systems or objects are, therefore, brought back into an as good as new state after each repair. Standard results in renewal theory may then be applied for determining optimal maintenance policies. In practice, there are many situations in which this assumption cannot be made. The quintessential problem with imperfect maintenance is how to model it. In many cases it is very difficult to assess by how much a partial repair will improve the condition of a system or object and it is equally difficult to assess how such a repair influences the rate of deterioration. Kallen (2011) proposed a superposition of renewal process is used to model the effect of imperfect maintenance. It constitutes a different modelling approach than the more common use of a virtual age process.

Nishijima (2007) addressed the issue of optimization of reliability acceptance criteria for components of complex engineered systems with given criterion to acceptable system risk. To this end, first described how complex engineered systems may be modelled hierarchically by use of Bayesian probabilistic networks. The Bayesian probabilistic network serves as a function relating the reliability acceptance criteria of the individual components of the system to the risk acceptance criteria for the system. Thereafter, a constrained optimization problem is formulated for the optimization of the component reliabilities. In that optimization problem the system risk ac-

ceptance criterion defines the constraint and the expected utility from the system, is considered as the objective function.

During the design phase of a product, reliability engineers are called upon to evaluate the reliability of the system. The question of how to meet a reliability goal for the system arises

when the estimated reliability is inadequate. This then becomes a reliability allocation problem at the component level. Mettas (2000) estimated a general model for the minimum reliability requirement of multiple components within a system that will yield the goal reliability value for the system. The model consisted of two parts. The first part was a nonlinear programming formulation of the allocation problem. The second part was a cost function formulation to be used in the nonlinear programming algorithm. A general behavior of the cost as a function of a component's reliability is assumed for this matter.

In the exact method there are two classes for the computation of the network reliability. The first class deals with the enumeration of all the minimum paths or cuts. A path is a subset of components (edges and/or vertices), that guarantees the source and the sink to be connected if all the components of this subset are functioning. A path is a minimal if a subset of elements in the path does not exist that is also a path. A cut is a subset of components (edges and/or vertices), whose failure disconnect the source and sink. A cut is a minimal if the subset of elements in the cut does not exist that is also a cut (Hariri and Raghavendra, 1987; Ahmad, 1988). The probabilistic evaluation uses the inclusion-exclusion, or sum of disjoint products methods because this enumeration provides non-disjoint events. Numerous works about this kind of methods have been presented in literature (Lucet and Manouvrier, 1999). In the second class, the algorithms are based on graph topology. In the first process we reduce the size of the graph by removing some structures namely, polygon-to-chain (Choi and Jun, 1985) and delta-to-star reductions (Gadani, 1981). By this we will be able to compute the reliability in linear time and the reduction will result in a single edge.

The idea is to decompose the problem in to one failed and another functioning (Carlier and Lucet, 1996). The same was confirmed by Theologou & Carlier (1991) for dense networks. Satyanarayana & Chang (1983) and Wood (1985) have shown that the factoring algorithms with reductions are more efficient at solving this problem than the classical path or cut enumeration methods.

MAIN FOCUS OF THE ARTICLE

Assume a production system having multiple robots and work stations leading to a complex system. To evaluate the reliability of this system a network of components is considered configuring a complex reliability network. A robotic network is considered which has perfect vertices and imperfect links. It means path links may fail with known probability. We obtain the reliability of the given network by using an exact method and with binary decision diagram. Binary decision diagram based reliability evaluation involves three main steps. First, ordering the given path link. Second, generate the reliability function with the help of min-paths from source to sink. At last, apply Shannon's decomposition to compute the reliability of the given network. The reliability evaluation under study is in two states of working and breakdown. Then, multiple robots are considered in two states. To handle such a complex problem in a network structured production system, binary decision diagram (BDD) is proposed. The reasons are: adaptability with network system; Boolean decision systems according to two states of the robots; flexible computational capability with increase of size of the system components. In the proposed BDD working state is shown by 1 and breakdown (stop working) is shown by 0. More details are given in next section.

Binary Decision Diagrams

Akers (1978) first introduced BDD to represent Boolean functions i.e. a BDD is a data structure used to represent a Boolean Function. Bryant

(1992) popularized the use of BDD by introducing a set of algorithms for efficient construction and manipulation of BDD structure. The BDD structure provides compact representations of Boolean expressions. A BDD is a directed acyclic graph (DAG) based on the Shannon decomposition. The Shannon decomposition for a Boolean function is defined as follows:

$$f = l \cdot f_{l=1} + \bar{l} \cdot f_{l=0} \quad (1)$$

where l is one of the decision variables, and f is the Boolean function evaluated at $l = i$. By using Shannon's decomposition, any Boolean expression can be transformed into binary directed acyclic graph. BDD are used to work out the terminal reliability of the links. Coudert and Madre (1992) found BDD usefulness in reliability analysis which was further extended by Rauzy (1993 and 2003). They are specially used to assess fault trees in system analysis. In the network reliability framework, Imai et al. (1999) have shown how to functionally construct the corresponding BDD. An alternate approach was shown by Singhal et al. (2010, 2011, 2012), to compute BDD based network reliability. Table 1 shows the truth table of a Boolean function f and its corresponding Shannon tree is shown in Figure 2. Sink nodes are labelled either with 0, or with 1, representing the two corresponding constant expressions. Each internal node u has two out-edges called 0-edge, and 1-edge. The node linked by the 1-edge represents the Boolean expression when $l_i = 1$, i.e. $f_{li} =$

1; while the node linked by the 0-edge represents the Boolean expression when $l_i = 0$, i.e. $f_{li} = 0$.

Maintenance department records the failures and thus probability distribution is obtained leading to reliability evaluation. Since we have a network of components in the production system being active or inactive (binary state), binary decision tree is configured. The following notations are noted for this purpose:

L_j : robot j th

F_u : robot performance function

K : counter for robots; $j=1,2,\dots,K$.

SOLUTIONS AND RECOMMENDATIONS

Let's consider an example for the implementation of the proposed robotic system reliability evaluation. A production system having 9 work stations and 4 robots to process material handling in considered. The movement paths of the robots are in series and parallel with respect to the sequence of work stations they service. If two robots have a common path except source (S) and sink (T) nodes, then they are series and otherwise they are parallel. A schematic presentation of the system network is shown in Figure 3.

According to the series/parallel structure of the components the corresponding reliability block diagram is drawn in Figure 4.

Figure 2. Binary decision Tree of the given Boolean Function

Figure 3. A schematic presentation of the robotic system

Box 1.

Figure 4. A reliability block diagram

Also, the corresponding table of truth for the 4-robot system is given in Table 2.

According to the truth table, a binary decision tree is formed and shown in Figure 5.

While there are two states of working (S) and failure (F) for each robot, 16 cases are formed as given below. Since robots are similar, the failure rate is considered 0.02 for all of them, i.e., $p(L1)=p(L2)=p(L3)=p(L4)=0.02$. Finally, the reliability of each case considering binary decision tree and Shannon decomposition formula are as follows:

$$\begin{aligned}
 L1_F L2_F L3_F L4_F: & 1-[(1-(0.02*0.02*0.02))*(1-0.02)]=0.020007 \\
 L1_S L2_F L3_F L4_F: & 1-[(1-(0.98*0.02*0.02))*(1-0.02)]=0.02038416 \\
 L1_F L2_S L3_F L4_F: & 1-[(1-(0.02*0.98*0.02))*(1-0.02)]=0.02038416 \\
 L1_F L2_F L3_S L4_F: & 1-[(1-(0.02*0.02*0.98))*(1-0.02)]=0.02038416 \\
 L1_F L2_F L3_F L4_S: & 1-[(1-(0.02*0.02*0.02))*(1-0.98)]=0.98000016 \\
 L1_S L2_S L3_F L4_F: & 1-[(1-(0.98*0.98*0.02))*(1-0.02)]=0.03882384 \\
 L1_S L2_F L3_S L4_F: & 1-[(1-(0.98*0.02*0.98))*(1-0.02)]=0.03882384 \\
 L1_S L2_F L3_F L4_S: & 1-[(1-(0.98*0.02*0.02))*(1-0.98)]=0.98000784 \\
 L1_F L2_S L3_S L4_F: & 1-[(1-(0.02*0.98*0.98))*(1-0.02)]=0.03882384 \\
 L1_F L2_S L3_F L4_S: & 1-[(1-(0.02*0.98*0.02))*(1-0.02)]=0.02038416
 \end{aligned}$$

$$\begin{aligned}
 L1_F L2_S L3_S L4_S: & 1-[(1-(0.02*0.98*0.98))*(1-0.98)]=0.98038416 \\
 L1_F L2_F L3_S L4_S: & 1-[(1-(0.02*0.02*0.98))*(1-0.98)]=0.98000784 \\
 L1_S L2_S L3_S L4_F: & 1-[(1-(0.98*0.98*0.98))*(1-0.02)]=0.94236816 \\
 L1_S L2_F L3_S L4_S: & 1-[(1-(0.98*0.02*0.98))*(1-0.98)]=0.98038416 \\
 L1_S L2_S L3_F L4_S: & 1-[(1-(0.98*0.98*0.02))*(1-0.98)]=0.98038416 \\
 L1_S L2_S L3_S L4_S: & 1-[(1-(0.098*0.98*0.98))*(1-0.98)]=0.99882384.
 \end{aligned}$$

This way the reliability of a complex robotic system is computed. According to the obtained solutions in cases having more working components the reliability of the system is more. Thus the maintenance department should conduct a predictive maintenance program to keep components in working states to obtain more system reliability. Also, management can decide on reserve system in which some components are ready to be replaced with the broken down ones when needed. This way, the system is available most of the time. Of course, providing reserve components incur costs to the system but economic analysis associated with reliability evaluations help decision makers in this purpose. Generally, reserve system is justified due to the benefits achieved by a reliable system. Another recommendation could be the configuration of the work stations and robots in the production network so that more parallel sub-systems are formed. In parallel sub-systems the availability and thus the reliability of the

system is more due to more choices for robots to serve in a sequence free manner. While in series system the whole system may be influenced by one component breakdown.

FUTURE RESEARCH DIRECTIONS

Reliability assessment in the current advanced manufacturing systems is significant due to large amount of economic investments. Also, complex system (network) of components motivates developing efficient methods for performance analysis. Binary state systems are the simplest for which is extensively considered in production systems due to maintenance consideration. Combining stochastic process computations such as branching processes with high performance artificial intelligence techniques help the decision makers to obtain more confident results. The research in this field is toward applying neural network methodologies for computing reliability in stochastic and uncertain components specifically in automation applications.

CONCLUSION

An efficient method for generating the BDD of a robotic complex system has been proposed. The reliability has been evaluated via BDD and by applying a truth table and Shannon decomposition formula. A network of robots in a production system was considered. The block diagram was configured and employed for developing different cases of the system performance. Considering the binary decision tree the computations of reliability for each case was presented.

KEY TERMS AND DEFINITIONS

Binary System: A system in which information can be expressed by combinations of the digits 0 and 1 or a system consisting of two parts.

Complex System: A system having multiple components and sub-components making it difficult to evaluate its performance.

Failure: Failure is the state or condition of not meeting a desirable or intended objective, and may be viewed as the opposite of success.

Reliability: Reliability is the ability of a system or component to perform its required functions under stated conditions for a specified period of time.

Repair: To restore to sound condition after damage or injury.

Robot: An automated driverless controllable vehicle which is used as transportation and transferring device.

Work Station: Work station is an industrial unit for processing a function allocated due to the manufacturing plan using input material and delivering semi-produced or final products to the next manufacturing unit.

A Bio-Inspired, Distributed Control Approach to the Design of Autonomous Cooperative Behaviors in Multiple Mobile Robot Systems

Gen'ichi Yasuda

Nagasaki Institute of Applied Science, Japan

INTRODUCTION

This chapter concerns the design and implementation of bio-inspired control architectures for intelligent multiple mobile robot systems. In a multi-robot system, robots work together efficiently to accomplish tasks intrinsically distributed in space, time, or functionally. Due to the cost of increasing system complexity especially in control and communication, it is difficult to implement a centralized controller for multi-robot systems under unknown dynamic environments (Khoshnevis & Bekey, 1998; Klavins, 2003). Focusing on building control systems for intelligent mobile robots, this chapter presents a non-centralized, behavior-based methodology for autonomous cooperative control, inspired by the adaptive and self-organizing capabilities of biological systems, such as turning over behavior of starfishes (Suzuki, et al., 1971), which can generate robust and complex behaviors through limited local interactions in the presence of large amount of uncertainties (Pfeifer et al., 2007; Salazar-Ciudad et al., 2000; Shen et al., 2004).

Traditionally, the fundamental feature of asynchronous concurrent processes in robot control systems was already employed in the control system design as a centralized control, where a single multitask operating system controls different programs, or processes, to be performed concurrently, such as locomotion control, environment recognition, path planning, decision making in uncertain environments, etc. under a set of tim-

ing requirements. From the view of asynchronous concurrent processes, modularity and localization of control are critical issues in control system design. Thus, in this chapter, the distributed control architecture, based on discrete event systems as a formal approach, is configured as a collection of asynchronous, concurrent processes in a hierarchical but non-centralized way, and consequently it can be developed in such a way to reduce the programming requirements. While actuator and sensor controls, such as vehicle control and image processing, are prerequisite at the lowest control level, a unified and systematic methodology has been developed to combine given techniques for controlling the robot motion and for integrating sensory information at some higher control levels, into one complete robot control system for real-world robotic applications.

Asynchronous concurrent processing on parallel distributed architecture can support the coordination between the global intelligence or control center and the set of local centers as well as among local centers (Alon, 2006; Kondacs, 2003; Taylor, 2014), where each local center supports at least one robotic module and each module is governed by only one local center. The channel between two local centers is also open for emergent responsive motions. The object-oriented concept can be employed to support the system requirements for modularization of robot intelligence including the reconfiguration of global-local interaction through parallel distributed processing, utilizing the traditional technique in spatial and kinematic

DOI: 10.4018/978-1-5225-2255-3.ch592

planning, and dynamic control as building blocks (Werfel, 2004). Thus, the distributed autonomous control system design based on asynchronous concurrent processing would provide the necessary flexibility to overcome some of limitations of current intelligent mechatronic system design. Furthermore, the flexibility for different tasks and control environments can be increased, by integrating various robots and components into systems in a heterogeneous robot environment where each robot has its own kinematic structure and programming language.

This chapter describes the hierarchical task specification in terms of event driven state based Petri net modeling (Yasuda, 2014), where the robotic task model is hierarchically decomposed into subtasks in such a manner that every subtask, represented as a subnet of the task specification net model, is assigned to a local module, based on the geographical distribution of the local centers.

BACKGROUND

The control of autonomous robots evolves from the control of an individual robot to the self-coordination of a group of robots that interact and function together to form a social group, where the interactions among robots can produce behaviors that no single robot can accomplish without the other individual robots. In recent studies focusing on cooperation of distributed autonomous multiple robot systems, the cooperation strategy is mostly based on distributed problem solving and distributed decision (Shi et al., 2012), like a human individual, considering each of these robots as an agent in the social interaction. The behavior of a robot can extend beyond itself to include other individual robots. However, a robotic task is considered as a succession of many primitive reactive behaviors or actions, each activated with some events or external sensing information. For example, in collision avoidance among mobile robots and transporting many discrete litters by multiple robots, each robot gets some information

about other robots by communication, and then uses the information for making a distributed decision. Collective execution of cooperative tasks with dynamic constraints, such as large object manipulation, may have more dynamic factors. Because the robots which are working on manipulation, interfere each other dynamically through the manipulated object, the increase in communication required for achieving harmonious cooperation between moving motion and manipulating motion in a robot makes the control system difficult to realize in a pure distributed system. So, some global information about the object and robots should be collectively reflected from sensors on each robot, so that all the robots can react synchronously to environmental change or upper level mastering event in real time.

The behavior-based approach emphasizes the decomposition from a task to a set of pure reactive behaviors for real-time control, which implies fully parallel control architecture composed of multiple behavior modules. The important problem is that, in cases where control should be shared between multiple modules, the output would result from the arbitration of multiple conflicting module outputs. The activation and inhibition mechanism of conflicting modules composes the intelligence center of the distributed control system. The behavior network is another example where a behavior is chosen by comparing and updating activation levels for each behavior. Each enabled behavior selects the required actions, computes run-time parameters, and generates a bid describing the appropriateness of the behavior. The most appropriate behavior is determined in a distributed manner through inter-behavior bidding without any centralized mechanism. Although the problem of arbitration between behaviors is better solved in a centralized system with some knowledge, the arbitration occurs only for specific cases in a system where tasks are partially ordered with a planner. Because, in dynamic environment, a robot needs to quickly decide what to do and how to do it, the deliberative components must keep pace with changes in the environment to reactively

Figure 1. Hierarchical and distributed control architecture for mobile robot activities in exploring and mapping task

produce intelligent behavior where each behavior is also responsible for planning the required actions, so that fixed computational resources need to be distributed among the behaviors. Thus, the reactions, composed of reflex, local control and replanning, should run in parallel on hierarchical software architecture, in order to insure reactivity at every level. Behavior and other control modules should have their own control autonomously with knowledge grouped at each level in order to have a better management of conflicts.

HIERARCHICAL DISTRIBUTED ARCHITECTURE FOR BEHAVIOR BASED MOBILE ROBOT CONTROL

The conceptual framework of hierarchical and distributed control software architecture for integrated deliberative planning and reactive execution of mobile robots is shown in Figure 1. The software architecture is constructed upon

the distributed hardware structure, where each microcomputer-based intelligent device for sensing and actuation is connected via a serial bus. The software control structure is not only functionally parallel/distributed but also hierarchically distinguished for effective development of a robot control system, considering the different abstraction levels that correspond to the different real-time constraints and the complex nature of its signals. The distinction of planning and reactive control is based on the different time scales of interaction. A view of an experimental mobile robot is shown in Figure 2.

The major subsystems of the hierarchical architecture are the coordination and control layers, which are implemented on the system controller. Each control module at the control layer provides for a dynamic link between perception and action to control robot motion using external sensory data through input lines carrying data from sensor modules, where output lines issue commands to effector modules or send data to another module.

Figure 2. View of an experimental mobile robot

Sensing information is organized into several levels corresponding to increasingly complex representations and abstract interpretations. Any representation of sensing information at a level may be used for event detection to achieve the condition test by managing all the conditions at the level, and to send a signal to the upper layer whenever the condition is met. For example, the range-finding module manages a belt of range sensors, to process their echoes, and to verify conditions or events, where three levels of interpretation are considered: point distance threshold level, segment location level, poly-line recognition level. Similar to the levels of interpretation of sensing information, there are different levels of actuation command. The effector module to drive the robot's motorized wheels with internal sensors is organized into trajectory control level and tracking control level. The trajectory control level receives a path (straight or circular), and generates a smoothed sequence of straight lines and clothoid arcs. The tracking control level tracks a point, supplied by the trajectory control level, by servoing of the robot motion using perceptual data. For example, the robot can detect and avoid obstacles while carrying out wall following or object pattern tracking, through cooperative parallel execution of the obstacle avoidance and the motion

execution modules. For primitive goal-directed action control, besides motion execution modules, the control layer embodies landmark and obstacle detection, self-localization, and self-referencing modules. Basically, for the same actuator system, such as arm, leg and hand, one motion execution module can run at a time and their parallel or sequential execution can be decided with efficient multi-agent system computation based on mutual exclusion to a limited computer resource.

The coordination layer is in charge of the overall behavior control as a whole, coordinating the control modules by sending the activity start events and waiting for the incoming events and clock events which have a global influence on its achievement. The coordination layer is built as a set of concurrent layers that embodies the different behaviors. Behavior modules have specific inputs and outputs: sensory and actuation information. They may share some of the input information with other modules. The access to the hierarchical sensory information is managed by the shared information manager. While a behavior module is activated by its specific inputs, it is executed by the attached executor as a software agent. The set of active behaviors and their resulting cooperation is controlled by the incoming events.

The task organization layer generates a task specification with a global planer based on specified task plan. Generally each step of a plan corresponds to a task, while a task is represented as a succession of commands written with some command language. Its event based task description coordinates the system behaviors or subtasks: environment map building, global navigation, and particular manipulating operations. At the task organization layer, global planning is executed as one small part of the main controller's nominal cycle of activities. A geometrical map of the local environment is built in the coordination layer. Given a set of target locations, the coordination layer plans a detailed medium distance local path to the closest target position only and executes this plan. Upon reaching this target location, its local map will change based on the perceptual

information extracted during motion. Only then the local path planner is triggered to generate a path from the new location to the next target location. When a reference object is detected by a vision sensor, a trajectory planner is triggered to generate the short distance motion for docking or manipulation.

MODELING AND DESIGN OF ROBOTIC TASKS

For the Petri net modeling of robotic activities, a place represents a condition or state of processes or resources. A transition corresponds to an event or action. The input places of the transition define the pre-conditions to the execution of the action. The output places define the results or post-conditions of the action (Milutinovic, et al., 2002). For real-time cooperative control of some robotic activities, a transition representing a robotic activity is decomposed into start and end transitions and a place representing the process, or the code associated to the activity. Temporal constraints, such as a delay, duration, time-out, or periodicity can be included in the start transition. If a place is an action place, a token placed in the place indicates that the state of the process corresponding to the place is holding. The execution starts when the place becomes marked. When the execution ends, the end transition is fired and the processing time is determined by external conditions. In our research, for compact representation of interaction with the environment, the extended Petri net adopts the following elements as input and output interfaces which connect the net to its environment: gate arcs and output arcs. A gate arc connects a transition with a status signal source (or places) in the internal or external environment, and depending on the signal, it either permits or inhibits the occurrence of the event. An output arc connects a place with a resource or external machine and sends a command signal to the resource.

An extended Petri net representation of robotic actions is specified using transition firing with

gate arcs based on the command/response concept. When the start transition is enabled, the transition triggering function is activated to check the input permissive gate signals and request the resources needed by the token. After the transition is fired, the initialization command is sent to the resource through the output signal arc. Next, after the initialization is finished, the acknowledge signal is sent from the resource through the inhibitive gate. Then, the token sends the associated parameters and action start signal to the resource. At the end of actions, the resource sends the signal status through the inhibitive gate. After the termination process, the resource sends the status to acknowledge the completion of the process through the inhibitive gate arc, and finally the resource is released, where the termination activity may be interlocked with another subtask in the system through the inhibitive gate arc.

Basically, from a task-oriented view of robotic activities, a robotic task is defined as a collection of state changes of the objects or the robot's environment in a system, and a task can be performed in a sequence of these subtasks and each subtask, in turn, will take place according to the behaviors dependent on the successive sensor data. Primitive behaviors can be enabled if their pre- and post-conditions are fulfilled, and their executions are triggered by their specific signals. When two or more behaviors are enabled, one of them should be selected because they use the same resource or motion execution module. So, the net model should be enabled in parallel with the resource place. By the analogy with instinct behaviors in animal ethology (Tinbergen, 1951), complex behaviors are viewed as a resultant behavior of different kinds of robotic actions combined using control structures such as sequential, conditional, iterative, and concurrent constructs. Given all the possible actions, the resultant, desired behavior is brought about by a set of explicit rules of transitions between actions through sensor information, leading to the unexpected or surprising appearance. Top-down decomposition and bottom-up construction, referred as refinement and abstraction by place

or transition substitution, support the definition of activities and their associated resources, offering a vertical structuring mechanism similar to object composition in object-oriented language. The hierarchical structuring mechanism can be defined in static or dynamic form, corresponding to the concept of macro and procedure invocation, respectively. For a macro-place, where all the arcs are connected to transitions, the boundary of the subnet is composed by places, and a set of interface ports are used to connect the net and its subnets for flat (non-hierarchical) or hierarchical simulation. Bottom-up, horizontal net composition is defined as the merging of nets into a single net one through transition or place fusion to support reusability of net modules already available. High-level net folding based on tokens and node vectors is seen as a kind of fusion.

Petri nets have been applied to a simple mobile robot task of sensory environment exploring and mapping, composed of obstacle avoidance, target seeking and wall following behaviors (Nishiwaki, et al., 2014). Upon these primitive behavior modules, a Petri net based approach was applied to coordination of several concurrent activities of modules for the higher-level behavior or task. As shown in Figure 3, the overall net model is conceptually configured through sequential constraints between behavior modules defined based on the task specification sent from the task organization layer so that the behaviors of the whole system are brought about for achieving the global task specification. The firing of transition t_1 , representing the sensing action, models the updating of data from the range sensors. The places that receive tokens from the sensing module model data information checked and supplied about obstacle and wall distances and directions and target positions. If an obstacle is detected as indicated by the firing of transition t_3 , the obstacle avoidance behavior takes place. Otherwise, if no obstacle is found as indicated by the firing of transition t_4 , after the firing of transition t_5 , the firing of transitions defining which behavior is initiated depending on current sensory data in exploration and mapping

is brought about. The activity of each behavior module is represented by a place in the net. In Figure 3, the robotic task is divided into three behaviors, “Target seeking”, “Target following”, and “Localization and mapping”, where each behavior module is triggered by particular sensing information, plans the corresponding actions, calculates the strength, or bid, of the behavior command using the importance of the sensing information and the specified priorities among the different behaviors. The motor control mode models the motion states of the mobile robot according to the behavior decision, and is stored at the lowest level in the hierarchical shared memory.

Figure 3. Overall Petri net model composed of behaviors involved in exploring and mapping task

Thus, the overall behavior will take place through the activation of the behavior modules dependent on the successive sensor data, while the obstacle avoidance behavior is always concurrently checking whether an obstacle is present or not.

Actually, behavior “Target seeking” starts when the robot starts environment search, that is, the corresponding transition t_5 fires. Since a wall is detected, as indicated by the firing of transition t_6 , behavior “Target following” begins, that is, the robot keeps following the wall using range sensors and builds a local map. The end of the behavior and the start of behavior “Localization and mapping” take place once the wall is no longer present as indicated by the firing of transition t_{10} , that is, the robot performs the localization and mapping task. Thus, the robot behavior may oscillate between the exploring and mapping behaviors. At the end of “Localization and mapping”, as indicated by the firing of transition, if the whole environment in the global map is searched, then the mobile robot stops as indicated by transition t_{13} and place “End”, if not the next target is determined and the search and map behavior is continued as shown by transition t_{14} .

Figure 4 shows the detailed net model of the wall following behavior in exploring and mapping. When the behavior is active, it carries out the two primitive behaviors, target tracking and local mapping, continuously using scanned distance measurements information. The primitive

behaviors must start and end simultaneously, synchronizing with events for sending and receiving the required distance information. The target tracking module requests wheel control and distance measurement control modules to perform tracking control using scanned measurements. The locations of sensed points are corrected taking into account the motion of the robot to estimate the direction of the wall with respect to the robot coordinate. The measurement module integrates the most recently sensed points to have complete updated data about the wall direction. The local mapping module updates the local map with the current wall direction. If the wall is not found, the two behaviors terminate the tracking control and local map building. Then the localization behavior is activated to localize the robot on its own local map and transfer the positional information to the global map builder. The current goal or subgoal and the current state of the robot are accessed and read as global, shared variables using synchronous sending and receiving actions between associated modules based on mutual exclusion. The synchronous actions are represented as a shared transition for synchronous communication. The target tracking behavior is a periodic process, while the local mapping behavior is executed each time that a new location of wall comes from the tracking module. The wall following behavior is executed not periodically, to react to environment status change as a supervising process, such as

Figure 4. Petri net model of wall following behavior with parallel constructs

obstacle detection or command reception from the upper level. When the behavior is started, a triggering function is activated to detect the termination condition. A triggering function is also activated to detect obstacles, such that if an obstacle is encountered, the function is fired and the robot stops. For path tracking using ultrasonic range sensor signals, if the straight-line path to the target is free, the target position is redirected to the sensor module and obstacle avoidance is stopped.

SOFTWARE CONTROL OF MOBILE ROBOTS

All the modules in the coordination layer are realized as asynchronous concurrent processes activated under a multitasking operating system. The local planning module receives a task plan, parses or analyses each task into a command language composed of a set of command statements. A command represents a behavior or function provided by specified control modules in the

control layer. Then the behaviors in the coordination layer are activated as a whole, taking into account events that might have a global influence on its achievement, coordinating the activities of control modules such that they are in accordance with transition firing in the hierarchical net model. Thus, the coordination layer carries out tasks and manages robot resources, by detecting and arbitrating conflicts or multiple access to a sensor/effector module. The robot localization may use different resources to provide robot position, such as odometry, laser or vision data, and some external or contextual knowledge. When an event occurs at any control module, the module interrupts the system controller. The behavior module receives the event and updates corresponding net model data, or enabled transitions, in the hierarchical shared memory, where the states of activity of all modules in the system are managed with the associated input and output event identifiers and the parameter list, so that the information provided by sensor modules may be used by dedicated modules at several levels of interpretation. Using the

Figure 5. Petri net model of communication protocol between operation and control modules in hierarchical Petri net

shared memory and an environment map created by a global map manager, the behavior module processes the event and generates global actions for navigation. Then, the behavior module requests commands to the relevant control modules and these modules perform real-time control actions according to the commands, as shown in Figure 5.

A token points to a command statement and contains information related to its current execution status. Triggering functions for transition firing play a central role in the activation and inhibition of the behavior modules. To provide for event based programmable reactivity composed of three stages, that is, reflexive reaction, action determined by the current task and task re-planning, a logical formula of conditions to be tested for transition firing is associated to each behavior or control module. If the conditions are true, a set of reactive actions are carried out and commands specified by the token, including control loop, are sent to and executed by the specified modules or resources. At the same time, the transition triggering functions of conditions for ending of the actions, which are also specified by the token, are activated. Robot resources such as sensor and effector modules are managed to detect and arbitrate conflicts by multiple access. If an error occurs during task execution, the origin of the error is located and a procedure or a sequence of intermediate actions to reach the sub-goal, is inserted in the current task for possible repairs locally handled at the control level or re-planning using global knowledge of the whole plan at the task level.

FUTURE RESEARCH DIRECTIONS

The main disadvantage of using low-level Petri nets has been overcome with the use of hierarchical, modular Petri nets. Practically the decomposition strategies for obtaining subnets may be adopted according to the number of processors, the similarity structure of the subnets or the geographical distribution of the subsystems. To make further

improvement on the real-time performance, parallel and distributed execution of the Petri nets in robot controllers should be augmented, such that the net model is maximally partitioned into subnets in such a manner that every subnet may be assigned to an agent capable to control one active component or effector, involving one subsystem or workplace and avoiding situations where two or more agents handle the same subsystem. Innovative multi-core parallel processing architecture with FPGAs for efficient parallel execution is now being employed for the development of hierarchical and distributed Petri net models in the robot controller, in order to overcome limitations on the status of implementation due to hardware and low-level software, such as inter-process communication.

CONCLUSION

This chapter presents a design methodology of behavior modules for discrete event distributed control of autonomous mobile robot systems. A modular, Petri net based behavioral control software has been implemented in accordance with a hierarchical distributed microcontroller based hardware structure. The behavior modules with respective pre-conditions and post-conditions can be dynamically connected in response to status event information from action control modules at the lower level to achieve the specified overall task. The approach involving planning, control and reactivity can integrate high-level command input with the behavior modules through the distributed autonomous control architecture, to correspond better to the needs of general purpose mobile robots.

KEY TERMS AND DEFINITIONS

Behavior: Sequence of interactions between an organism and its environment where the actions affect its own perceptions.

Environment Mapping: Building a natural internal representation of a robot's environment including places in the environment and other information such as target objects and obstacles.

Hierarchical Structure: Complex system structure organized into a hierarchy of levels of

abstraction such that a system at one level becomes a building block for the system defined at the next higher level.

Localization: Processing to maintain an on-going estimate of the location of a robot with respect to the environment map.

Modularity: Capability of reuse of the programs describing the construction of substructures as if they were subroutines that can be invoked multiple times.

Multi-Agent System: A system composed of multiple cooperative agents or robots, where each controls its own local subsystem, communicating with other agents within limited range, to achieve a common goal collectively.

Subsumption Architecture: Control architecture consisting of a number of behavior modules that directly map sensation to action, arranged in a hierarchy similar to motor patterns used in animal ethology, where lower levels have an implicit priority over higher levels.

Improving Dependability of Robotics Systems

Nidhal Mahmud
University of Hull, UK

INTRODUCTION

The use of robotics systems is widespread and spans a variety of application areas. From health-care, to manufacturing, to nuclear power plants, to space missions, these systems are typically conceived to perform difficult, dangerous or critical tasks. The nature of such tasks (e.g., surgery operations, radioactive waste clean-up or space mining) places high demands on the dependability of robotics systems.

The preoccupations in the dependability of robotics systems are not new. Fault Tree Analysis (FTA; Vesely, 1981) and Failure Modes and Effects Analysis (FMEA; IEEE Std.352, 1987) are among the most often used techniques in various domains of robotics. For instance, Visinsky, Walker, and Cavallaro (1993) describe the use of FTA for robots operating in remote and hazardous environments. Other fields of application include industrial robots like in Karbasian, Mehr, and Agharajabi (2012), and modular and swarm robots like in Murray, Liu, Winfield, Timmis, and Tyrrell (2012).

The widespread use of FTA in the dependability assessment of complex systems is mainly due to the flexibility and ease of use of the fault trees. These are static (i.e., 'pure' Boolean) models, and therefore enable the use of efficient Boolean calculus in the elimination of component failures that are irrelevant to the total failure of the system. This logical reduction (known as qualitative analysis) simplifies the process to produce overall probabilities of system hazards (i.e., quantitative analysis). Nevertheless, such convenience comes with the loss of the significance of the sequencing

of failure events—i.e., the dynamic features often exhibited by modern systems cannot be captured by combinatorial models like this type of fault trees.

Robotics systems are certainly not an exception when it comes to sequence-dependent failures. For example, preclusion of the dynamic aspects due to the use of static fault trees in the analysis of modular robotic systems is clearly noted in Murray et al. (2012). To overcome such drawback, an alternative can be the utilization of fault trees that are extended with capabilities to capture the dynamic features. A well-known example is the Dynamic Fault Tree (DFT) approach (Dugan, Bavuso, & Boyd, 1992). This method was primarily conceived for quantitative analysis, which is often state-based (i.e., Markov analysis which is based on state transition diagrams [Markov models] is the DFT most prominent solving technique). That is, the full power of the Boolean methods was sacrificed here, especially when it comes to analyzing the dynamic parts of the system at the level of the fault tree (i.e., reducing the DFT).

Theoretically, some later research efforts have provided workarounds to the question of FTA with dynamic aspects. To deal with it, a technique which is relevant to this article consists of extending the Boolean methods with temporal logic calculus. In this connection, a set of temporal laws that enable qualitative analysis of fault trees extended with dynamic features can be found in Walker and Papadopoulos (2009). In the same vein, the algebraic formalism in Merle, Rousset, Lesage, and Bobbio (2010) proposes formal descriptions of dynamic behaviors and provides proofs of a number of theorems useful for the qualitative analysis of this type of fault trees. The

latter approach also deals with the corresponding probabilistic algebraic analysis.

In practice, automation of such advanced FTA as part of integrated dependability and systems engineering processes requires an automated generation and synthesis of these fault trees from failure behavioral models that are linked to the system specifications. The work in Mahmud, Walker, and Papadopoulos (2012) describes a suitable approach to generating and synthesizing fault trees that preserve the significance of the event-order from hierarchical models. Application areas for this approach include the automotive domain (Chen, Mahmud, Walker, Feng, Lönn, & Papadopoulos, 2013). More details about integration in an extended FTA through a Model-Based development process can be found in Kolagari et al. (2015).

In this article, emphasis is put on the significance of the sequencing of failure events and its implications in dependability analysis of robotics systems using FTA. Accordingly, a suitable technique for automated generation and synthesis of extended fault trees from system models is presented. Furthermore, we outline a novel approach to automated reduction of these fault trees. The article is structured as follows: the background section provides a literature review and highlights the relevant approaches to generating and synthesizing fault trees from systems models. The next section outlines an algorithm for the logical reduction of fault tree algebraic expressions that are extended with temporal semantics. Then, an advanced fault tree synthesis approach is presented in the following section. Finally, we present some future research directions, then we conclude.

BACKGROUND

A number of approaches to generating fault trees from system models can be found in the literature. However, a special focus is put on automata representations of the dysfunctional behaviors of systems from which the fault trees get generated.

In this regard, the existing approaches fall into two main categories. The first category concerns the generation of static fault trees; it includes approaches that have been used in the context of influential modeling languages like Altarica (Rauzy, 2002) and AADL (Joshi, Vestal, & Binns, 2007). The former has been used in several aerospace projects including Airbus civil aircraft programs. The latter is increasingly being accepted by the aerospace community as a future standard. Moreover, there have been efforts recently to generate static fault trees from modeling languages specific to robotics systems, e.g. RobotML (Yakymets, Dhouib, Jaber, & Lanusse, 2013).

The second category of methods for fault tree generation includes approaches to generating dynamic fault trees (Dehlinger, & Dugan, 2008), and fault trees that are extended with the significant temporal information about the order in which failure events occur (Mahmud, Papadopoulos, & Walker, 2010; Mahmud et al., 2012; Mahmud & Mian, 2013). The DFTs are solved quantitatively, often, by converting them into equivalent Markov models. Although, there have been efforts on the minimization of the obtained Markov models (Crouzen, Hermanns, & Zhang, 2008; Boudali, Crouzen, & Stoelinga, 2010), there is still less focus on qualitative analysis at the level of the fault tree in this method. However, the approach in Mahmud et al. (2010, 2012) and Mahmud and Mian (2013) allows to reduce the extended fault trees into equivalents which can be proven by using the temporal laws and theorems in Walker and Papadopoulos (2009) and Merle et al. (2010). This is a State Automata-based top-down deductive approach to Fault tree synthesis with Order-dependent behaviors, see SAFORA in Mahmud (2012). It has demonstrated its value in the framework of a rich model-based design founded on EAST-ADL (Chen et al., 2013; Kolagari et al., 2015). EAST-ADL is an approach for describing automotive electronic systems through an information model that captures engineering information in a standardized form (EAST-ADL, 2010).

Figure 1. Example of a SM path for the fault tree algebraic representation

The fault tree generation algorithm used in the Safora method is based on the approach outlined in Mahmud et al. (2010). It converts State Machines (SMs) showing transitions from normal to degraded and failed states into fault tree algebraic expressions. The transitions are labeled by failure events (denoted by upper case letters taken from the alphabet, e.g. A, B, C ... like in Figure 1) and the states that are relevant to the system dependability are marked (denoted by the lowercase letter q with the subscript m). An algebraic expression is a logical combination of failure events —using the logical AND (symbol ‘.’) and the logical OR (symbol ‘+’) — which can be extended with sequence information by using the Priority-OR temporal logic operator (symbol ‘|’). The latter, abridged as POR, can be found in Walker and Papadopoulos (2009) and represents a priority situation where one event must occur first and other events may or may not occur subsequently. For example, in the expression ‘A|B’, A occurs and B does not occur; or A and B both occur, but in sequence. Similarly, in A|B|C, A occurs first or alone; should B and/or C occur, this must happen after A, but the order in which B and C occur is unimportant.

A sequence can be represented by using only ‘.’ and ‘|’, which is a central issue in Mahmud et al. (2010). For example, the sequence A occurs first then B occurs second, which is denoted by $A < B$ (‘<’ represents the Priority-AND operator, which is abridged as PAND), can be represented by $A|B.B$, where ‘|’ has priority over ‘.’. Proofs of this equivalence and others that are useful to this article, like the following, can be found in Walker and Papadopoulos (2009) and Merle et al. (2010). We wish to note, though, that POR is referred to as non-inclusive BEFORE in Merle et al. (2010).

$$A < B \Leftrightarrow (A|B).B$$

$$A < B + B < A \Leftrightarrow A.B$$

$$(A|B).(A|C) \Leftrightarrow A|B|C$$

$$A|(B+C) \Leftrightarrow A|B|C$$

In Mahmud et al. (2010), the algebraic expression deduced from a marked state (denoted by q_m) in a SM is essentially the disjunction over the paths π from q_m to the initial state (traversed backwards) of the conjunction of the events that

label π . Moreover, an event E , which is incident from a state q in which paths diverge, will have priority over any other event E' , also incident from q , if and only if there is an event in the path starting from q through E to q_m , which is repeated (i.e., reappearing) in a path starting from q through E' to any state. For example, the (sub) path from q_i to q_m (top right of Figure 1) is essentially represented by $C.\pi_2$, where C is the sub-path's event which is incident from q_i and π_2 is the conjunction of the remaining events to reach q_m . Since C is repeated in a path divergent from q_i (slightly downwards in the figure), also there is an event F in π_2 which is repeated in another divergent path (to the bottom of the figure), C will then have priority over D and E , the other events which are also incident from q_i . Therefore, $C.\pi_2$ is now fine-tuned as $CIDIE.\pi_2$. Similarly, $A.\pi_1$, to the left of Figure 1, is essentially the algebraic representation of the sub path from q_0 (i.e., the initial state) to q_i . This representation is also fine-tuned into $AIB.\pi_1$ since there is an event B that is repeated in a divergent path. Therefore, the full path from q_0 to q_m is algebraically represented by $AIB.\pi_1.CIDIE.\pi_2$, and without any loss of the significance of the event order. There might be other paths reaching q_m , which are denoted as disjunctions (sums) of conjunction (product) terms. Thus, the marked state expression is directly obtained in a standard sum-of-product canonical form like in Equation (1), which is convenient for the logical manipulation thereof.

$$q_m = \sum \left(\prod E_i . \prod (E_j | E_k) \right), j \neq k \quad (1)$$

where ' Σ ' and ' Π ' represent respectively the Boolean 'OR' and 'AND'.

REDUCTION ALGORITHM

In this section, we propose an algorithm for the logical reduction of the generated algebraic expressions. The algorithm is demonstrated on

a primary-standby (PS) redundant system, like the example in Figure 2 (a). "A" is the primary component, "B" is the backup, and "S" is a monitoring sensor whose role is to activate B upon detection of a deviation from the output of A (e.g., omission of output). "I" represents the input to each of the two redundant components, and "Out" is the system output. Out must receive input from either A or B for a continuous operation of the system. This pattern is not uncommon in dependability-critical systems as A and B can be any sensing, control or actuating device. A SM example which describes the PS failure behavior is shown on Figure 2 (b), where $X \in \{A, B, S\}$ denotes an internal failure (i.e., basic event) of the corresponding component to the left of the figure. For the sake of clarity, the SM is simplified by assuming that input I is always provided, Out has no failure mode on its own, and total failure states are all merged into one marked state (i.e., state 7). Figure 2 (b) shows that failure of either primary or backup component needs to be followed, whether immediately or not, by failure of the other unit in order to reach state 7. Also, failure of the sensor is relevant to the total failure of the system only if it occurs too soon—i.e., S fails before failure of the monitored (primary) component occurs. Otherwise, the system can still function in standby mode upon failure of A.

Application of the conversion algorithm outlined in the previous section gives the following algebraic expression for state 7, and in the form of a sum of Product Terms (PTs) as in Equation (1):

$$\begin{aligned} \text{state 7} = & B.SIB.AISIB + (\text{PT\#1}) \\ & A.BIA.SIBIA + (\text{PT\#2}) \\ & A.SIA.BISIA + (\text{PT\#3}) \\ & AIB.SIBIA + (\text{PT\#4}) \\ & BIS.AISIB + (\text{PT\#5}) \\ & AIS.BISIA (\text{PT\#6}) \end{aligned}$$

Notice that there are 6 product term expressions, each corresponds to one path reaching state 7.

Figure 2. (a) a primary-standby example system and (b) the corresponding failure behavior

In fact, each product term $\prod E_i \cdot \prod (E_j | E_k), j \neq k$ in Equation (1) is a sequence set. For example, $A.B|C = \{ABC, BAC, BCA, AB, BA\}$. In the 2-event sequences (i.e., AB and BA), C does not occur. In other words, $A.B|C$ is the set of all sequences of A, B, and C should C occur, subject to inclusion of any order in which A and B occur (logical AND) and exclusion of the order in which C occurs before B (due to the term 'B|C')—assuming that simultaneity of occurrences of events is due to common cause failures, e.g., a power failure which causes several components to fail at the same time. Such failures are treated separately and are assigned separate failure rates should they occur.

Concerning the expression of state 7, we have: PT#1 is the singleton $\{ASB\}$. Similarly, PT#2 = $\{SBA\}$ and PT#3 = $\{BSA\}$. However, PT#4 = $\{SA, SAB\}$, PT#5 = $\{AB, ABS\}$, and PT#6 = $\{BA, BAS\}$. This way, each PT can be interpreted as a set of sequences as well as an algebraic expression—i.e., able to be manipulated by unions or by disjunctions (sums). Let's say we have n product terms denoted by $PT_i, i=1,2,\dots,n$. The canonical

form minimization algorithm proposed in (Merle et al., 2010) removes the redundant elements from the set S of all product terms.

$$S = \bigcup_{i=1}^n PT_i \quad (2)$$

According to Merle et al. (2010), a product term PT_i is redundant if:

$$PT_i \cdot \sum_{j \neq i} PT_j = PT_i \quad (3)$$

This algorithm aims at removing the completely redundant PTs. In many cases, we also need to check whether some events are irrelevant, especially when it comes to the order-sensitive part (i.e., the POR input events) of a PT. For instance, while the algorithm doesn't remove any $PT_i, i=1,\dots,6$ that compose the canonical form of state 7 of the PS example system, this doesn't mean that they cannot be reduced. Observing, e.g., $PT\#4 = \{SA, SAB\}$, it shows that B may not occur, or may occur but after A. The other

options to reach state 7 are via $PT\#2 = \{SBA\}$, which means that B occurs between S and A, and via $PT\#3 = \{BSA\}$ which means that B, S, and A, all occur in sequence. In other words, there is a sub-sequence SA common to $PT\#2$, $PT\#3$, and $PT\#4$; whether B occurs before SA, in the middle of SA, after SA, or doesn't occur at all, simply means that B is irrelevant and can be removed, thereby merging these product terms into a reduced (minimal) product term represented by $PT\#2,3,4 = \{SA\}$. But, the intermediate $PT_i, i \in \{2, 3, 4\}$ need not be removed yet, as they can serve to merge and reduce other PTs.

For example, $PT\#6 = \{BA, BAS\}$ can be merged with $PT\#2$ and $PT\#3$, then reduced into $PT\#2,3,6 = \{BA\}$ —since, overall, whether S is a prefix with BA (i.e., $PT\#2$), S occurs in the middle of BA (i.e., $PT\#3$), or S is a suffix with BA or does not occur at all (i.e., $PT\#6$), all show that S is irrelevant. Similarly, the $PT\#i, i \in \{2, 3, 6\}$ need not be removed yet until all iterations are processed. The last iteration concerns $PT\#5 = \{AB, ABS\}$ which can be similarly merged with $PT\#1$ and $PT\#4$, then reduced into $PT\#1,4,5 = \{AB\}$.

At this stage, state 7 (Figure 2b) canonical form is reduced (minimized) to $S = PT\#2,3,4 \cup PT\#2,3,6 \cup PT\#1,4,5$. That is, $S = \{SA, BA, AB\}$, which is algebraically written as:

$$Sal_g = A.S|A + A.B|A + B.A|B \quad (4)$$

The intermediate $PT\#i, 1 \leq i \leq 6$ are now each completely redundant with Sal_g (i.e., $PT\#i, Sal_g \supset PT\#i$) and can be removed as they cannot serve to reduce a PT any further.

Equation (4) can be written as $Sal_g = S < A + A.B$ which is graphically represented by the reduced SM in Figure 3a (with 3 full paths only instead of 6 initially), and by the reduced fault tree shown in Figure 3b where the gate to the top of the figure is a logical OR, to the left is a logical AND, and to the right is a Priority-AND.

For large systems, this approach is practical via composition. That is, failure expressions local to the system constituents are generated from their

Figure 3. (a) reduced SM and (b) reduced DFT of the PS example system

corresponding SMs, reduced as outlined in this section, and then synthesized into expressions of system failure conditions which likewise can be reduced further if necessary (Mahmud et al., 2012; Mahmud, 2012).

FAULT TREE SYNTHESIS

For instance, let us consider the example adapted from Visinsky et al. (1993) of two redundant sensors in a single robot joint. These are the primary and backup sensors which compose Subsystem1 of Figure 4a (i.e., the fault tree representation of the system). The basic events A and B (denoted by circles) correspond to the failures of primary and backup sensors, respectively. Subsystem1 fails if both sensors fail, hence the logical AND gate on the left-hand side of the figure. Moreover, the motion at the joint is coupled with another motion (Subsystem2) such that failure of either motion causes a joint total failure, and hence the logical OR gate to the top of the figure. However, Subsystem2 is not supplied with a fault tolerance mechanism. Thus, its basic event C is a single point of failure.

To increase the reliability of the system, the actively redundant sensors of Subsystem1 and the sensor of Subsystem2 all share the same spare unit S, as in Figure 4b —assuming that they are all functionally equivalent. S is supposed to take over any unit (A, B, or C) whichever fails first. In case a unit fails but cannot be rescued by the

Figure 4. (a) fault tree of a robot joint sensing system with active redundancy and (b) with an extra passive redundancy

spare, the output event of the corresponding spare gate to the middle of the figure becomes true (i.e., a fault event). A spare unit cannot take over a failed unit if it is also failed or is not available (e.g., it took over another unit that failed earlier). Such capability can be useful to implement cost-effective fault tolerance solutions that meet dependability requirements, especially if the sensors are unlikely to fail.

Now the order in which failure events occur can affect the overall outcome (i.e., total failure of the system). For example, if A fails first, it will be rescued by the spare, then if C fails second, in this case the spare is no longer available to take over C, and thereby causing a total failure. However, if C fails first, then it will be rescued by S, but a

Figure 5. Highly abstract state machine depicting the monolithic behavior of the system

subsequent failure of A is not severe since A is in active redundancy with B.

The dysfunctional behavior of this example system can be seen as an abstraction of an automata-hierarchy describing its embedded components. That is, it can be highly abstracted as in Figure 5, and the SMs of the constituents

Figure 6. Abstract state machine describing the dysfunctional behavior of Subsystem1

Figure 7. Abstract state machine describing the dysfunctional behavior of Subsystem2

located at lower levels of the hierarchy. An event causing a transition into a SM is typically either a basic event or a non-atomic event. The former means a component internal failure and the latter is due often to a fault caused by failures in some other components.

For example, Figure 5 shows that the system is initially working (state ON), but it totally fails due to propagation of errors caused by failures occurring downwards in the event causal chain,

i.e. from either Subsystem1 (Figure 6) or Subsystem2 (Figure 7).

Figure 6 shows that Subsystem1 is initially ON, but is seriously degraded as soon as one of its actively redundant units fails. A complete failure of Subsystem1 occurs upon the second severe failure (propagated from the other redundant unit).

Similarly, Subsystem2 fails upon a severe failure of its unit C, which is backed by S.

The spare unit S (Figure 8) is in passive redundancy and is, thus, inactive initially. Since

Figure 8. State machine of the spare unit S

Figure 9. State machine of the spare gate C

it is shared between spare gates A, B and C; it would take over any of these, whichever fails first (i.e., in response to the earliest deviation detected from the output of a unit). Alternatively, it may fail dormant.

Since all sensors of the robot joint sensing system exhibit similar dysfunctional behavior, we put emphasis on one unit, e.g. the spare gate C (Figure 9). Initially operational (state 'ON'), if C fails before any loss of the spare; then the situation is still safe, which means that the spare gate C is functioning in spare mode, in which case only a subsequent failure of S would worsen the situation. However, if C fails after the loss of the spare, the situation becomes severe.

Application of the generation algorithm on the SMs of the constituents and the reduction algorithm on the generated expressions, then synthesizing the obtained reduced expressions, ultimately yield the following result for the global failure condition, and without any loss of the significance of the event-order:

$$\text{Total failure} = S.C + A.C + B.C + S.A.B + C.A.C.B.$$

This result shows that the system fails due to any of the following causes: both S and C fail; A

fails then C fails; B fails then C fails; A, B and S all fail; or A and B both fail after failure of C.

FUTURE RESEARCH DIRECTIONS

Automation of the generation, synthesis, and analysis of advanced fault trees from RobotML models as part of integrated model-based design and analysis processes is an open issue. Moreover, there is still a lack of tools for the automated analysis of fault trees that are extended with event-order features. This is mainly due to the complexity of the manipulation as well as probabilistic assessment of this type of fault trees. Also, repairable events would be worth being considered as many users aim at modeling repairable systems. We wish to note, though, that the approach in this article does not totally preclude the existence of cyclic behaviors (failures and repairs)—i.e., after the transformation of the embedded acyclic behaviors into algebraic expressions, and the reduction thereof, the obtained results represent, therefore, minimal circuitless sequences onto which are grafted the repair circuits. However, this would imply analysis of (coherent) systems with perfect repair policy. Repairable systems with different maintenance policies are likewise worth being considered in future extensions of this work.

CONCLUSION

In this article, we outlined a lack of suitable techniques that generate, synthesize and analyze fault trees with the significant sequencing of events from models specific to robotics systems. Most of the existing work deals with static fault trees; less work is on generation of dynamic fault trees but with a focus on quantitative analysis. In this regard, this article puts emphasis on such important issue. The second contribution is a solution proposed for the generation then reduction of fault trees with more expressive power from automata descriptions of failure behaviors. We demonstrated the proposed algorithm on a primary-standby example system and shown the obtained analysis results. Moreover, a compositional approach to computing fault tree expressions of global failure conditions from the dysfunctional behavior local to the components of the system was presented. An example depicting a robot joint sensing system was used in the study. It has few components, but with very complex dependencies. This helped to illustrate the solution which sets the stage for a high-level of automation and integration of such advanced fault tree analysis with model-based design to effectively improve development of robotics systems.

KEY TERMS AND DEFINITIONS

AADL: AADL is an Architecture Analysis and Design Language standardized in 2004 by the Society of Automotive Engineers. It is used in the specification and analysis of the software and hardware architecture of real time embedded systems. AADL is mainly devoted to performance-critical aerospace and automotive systems.

Dynamic Fault Tree: Dynamic Fault Tree (DFT) was invented in response to a shortage in modelling sequence-dependent failures by using standard combinatorial fault trees. It thus added capabilities for capturing the dynamic aspects exhibited by modern complex systems. The DFT is designed primarily for quantitative analysis, in general by using Markov techniques. However, there has been less focus on qualitative analysis at the level of the DFT, i.e. determination of its (minimal) cut-sequences.

EAST-ADL: EAST-ADL is an Electronic Architecture and Software Technology Architecture Description Language for automotive embedded systems, which was developed by a consortium of universities and automotive companies. The language was further refined within the framework of the Model-based Analysis & Engineering of Novel Architectures for Dependable Electric Vehicles (MAENAD) EU FP7 project. Aspects covered by EAST-ADL include vehicle features, functions, requirements, variability, dependability, software components, hardware components and communication.

Failure Mode and Effects Analysis: Failure Mode and Effects Analysis (FMEA) is commonly known (and often used) as a bottom-up analysis technique. It proceeds by analyzing the system components individually, or sometimes collec-

tively, to inductively derive the consequences of their failures on the system. FMEA aims at addressing those effects and the technique is widely practiced in reliability engineering in high-hazard industries.

Fault-Tolerance Systems: Fault-tolerance enables a system to continue its intended operation in the event of faults in some parts of it. Fault-tolerance systems rely typically on redundant units. The redundant components can be active and operating in parallel, or passive but switched into active use upon failure of the primary units. They can also be designed to be shared by a number of functionally identical systems.

Fault Tree Analysis: Fault Tree Analysis (FTA) postulates a hazard (top event of the fault tree) which must be avoided. It then reasons backward to identify all logical combinations of events which could lead the system to that hazard. FTA can be quantitative by combining figures for component failure rates to calculate overall probabilities of system hazards. It can also be qualitative by eliminating the component failures that are irrelevant to the total failure of the system, and thereby attempting to produce minimal failure scenarios. FTA is widely practiced in reliability engineering and in high-hazard industries.

State Automata to Fault Trees: State Automata to Fault trees with Order-dependent behaviors (SAFORA) is a top-down deductive synthesis approach that computes expressions of global failure conditions from the dysfunctional behavior local to the components of the system (described as hierarchical state machines). The purpose is to accurately analyze the reliability of architectures and the technique is suitable for complex systems featuring dynamic aspects.

Robotics and Programming Integration as Cognitive–Learning Tools

R**Nikleia Eteokleous***Frederick University Cyprus, Cyprus*

INTRODUCTION

The technological improvements within the robotics field and its expansion to various fields such as medicine, industry and education, calls for robotics integration within the educational practice as learning tools. Alimisis (2012) supports that robotics draw the attention and interest of academicians, researchers and teachers in all educational levels as well as other stakeholders (policy makers and society leaders). Educational systems are responsible in preparing students (future citizens) for this ever-changing Hi-Tech, globalized, interconnected world. Numerous 21st century skills are reported in the literature as important to be developed by future citizens as the means to address the needs and demands of the society. Digital literacy is one of them and robotics and programing are becoming important elements within the educational settings. The students need to be provided with the opportunities to experience tinkering, fabrication, design and create technological artifact & interactive objects, construct their own meaningful projects, experience the scientific method of inquiry (Bers, 2008a; Bers, 2008b; Bers, Matas & Libman, 2013; Bernstein, Mutch-Jones, Cassidy, Hamner, & Cross, 2016; Eteokleous, 2016). Consequently, educators need to design learning environments enhanced by new technologies where students have the opportunity to experience them as cognitive-learning tools within their learning processes. In order for robotics to be integrated within the educational practice,

teachers need to be appropriately and adequately prepared by universities (for pre-service teachers at the undergraduate level and in-service teaches at the graduate level) and professional development authorities (for in-service teachers) (Vollsted, Robinson, & Wang, 2007).

The current chapter takes into consideration numerous research studies suggesting that robotics integration for educational purposes is an effective teaching method; arguing that if robotics activities are appropriately designed and implemented have great potential to significantly improve and enhance the teaching and learning process (Bauerle, & Gallagher, 2003; Benitti, 2012; Bers, Flannery, Kazakoff, & Sullivan, 2014; Eteokleous, Demeetriou, & Stylianou, 2013; Papert, 1993). Robotics in the classroom has taken a global momentum especially because of its positive contributions in the teaching of science, technology, engineering and mathematics (STEM) (Benitti, 2012; Bers, et al, 2014; Nugent, et al., 2009; Sullivan, 2008; Williams, Ma, Prejean, Lai, & Ford, 2007). Additionally, research has shown that robotics integration in education promotes the development of various non-cognitive skills, however extremely important life skills. For example, reasoning, problem solving, tinkering, sequencing, computational thinking, decision making, scientific investigation, collaboration, knowledge construction, critical thinking, creativity, communication (Bers et al., 2002; Benitti, 2012; Bers, 2008a; Bers, et al., 2014; Chambers & Carbonaro, 2003; Eteokleous, 2015; Eteokleous, 2016; Miglino, Lund, &

Cardaci, 1999; Resnick, Berg, & Eisenberg, 2000; Sullivan, 2008; Williams, et al., 2007; Williams, Ma, & Prejean, 2010).

Main Aim

Having in mind the above, the current study moves one-step further aiming to examine another aspect of educational robotics. The study focuses on robotics and programming as medium for developing cognitive skills in disciplines non-related to STEM. The purpose of the study is to examine how robotics and computer programming can be employed in the elementary classrooms (2nd to 6th grade) in order to achieve disciplinary learning objectives across disciplines (besides STEM). The following research questions guided the current study:

- In what degree did the disciplinary learning objectives are met? What did students learn when robotics and programming were used as cognitive-learning tools across disciplines?
- In what ways did teachers integrate robotics and programming across disciplines? What pedagogical and instructional approaches were employed by the teachers?
- What factors may influence robotics and programming integration as cognitive-learning tools in meeting disciplinary learning objectives?
- What were teachers' experiences, reflections, problems faced, and lessons learned from robotics and programming integration across disciplines?

BACKGROUND

Educational Robotics as a Cognitive - Learning Tool

It is suggested that there are two approaches related to robotics in education; 1) robotics as a

subject matter and 2) integrating robotics as a tool within the educational practice to achieve specific learning objectives (Eteokleous, et al., 2013). The integration of robotics as a subject matter, as an autonomous entity, and not within a well-designed lesson plan, provide limited educational potential and value. On the other hand, robotics integration as a learning tool, in selected teaching cases exploits its full potential; therefore, it upgrades and enhances the teaching and learning process and promotes school transformation (Eteokleous, et al., 2013). The intention of this approach is not to learn how to use the robotics package, and its programming software, but to use it as a tool within a specific educational context to meet disciplinary learning objectives (Bers, 2010; Bers, et al., 2014; Bernstein, et al., 2016, Eguchi, 2007, Eteokleous, et al., 2013). In other words, robotics is employed as a tool to teach and deliver concepts within various disciplines such as Mathematics, Engineering, Science, Physics, and even in non-technology related fields such as Language and Linguistics, Arts, Biology, Psychology (Bers, Ponte, Juelich, Viera & Schenker, 2002; Eguchi, 2007, Eteokleous, et al., 2013). *Robotics integration* in the teaching and learning practice is defined as the use of robotics by students as a tool that enhances their learning experience and supports the achievement of specific learning objectives (Eteokleous, et al., 2013, Thomaz et al, 2009).

This approach is related to the *learning with computers* or computers as mindtools (Jonassen, 1999a), where computers and overall technology is introduced as students' partners within the teaching and learning process. *Learning with technology* requires integrating computers and overall technology as mindtools in the classrooms to support constructive learning. Educators embed technology capacity in the context of ongoing teaching and learning in different school subjects. Thus, students learn how to use technology not as an end in itself, but as a tool that help them execute their tasks and promote the balanced development of their mental abilities. As a result they do not learn from technology, but technologies support

meaning generated by students. (Becker, 1993; Becker & Ravitz, 2001; Bielaczyc & Collins, 1999; CTGV, 2003; Cuban & Pea, 1998; Earle, 2002; Haugland, 2000; Jonassen, 1999a, 1999b).

A definition provided by Jonassen (1999b), successfully captures the essence of using various technology means as mindtools. He writes “Mindtools are computer-based tools and learning environments that have been adapted or developed to function as intellectual partners with the learner in order to engage and facilitate higher order thinking and learning” (p. 10). Jonassen (2000) was the first to provide the stimulus and motive for developing the appropriate theoretical background for the integration of robotics (technology) as an educational tool. He argued that technology and the various technological means can be considered as cognitive tools or “Mindtools”, which enhance and enrich the educational process (Jonassen, 2000; Chambers & Carbonaro, 2003).

The same approach can be applied for robotics and programming as part of the new technologies. By replacing the words *computer-based tools*, *computers* and *technology* with *robotics and programming*, the same approach is suggested by the current study to be used in the educational settings. Robotics and programming are employed as cognitive-learning tools to meet disciplinary learning objectives. For years, educational technology researchers argued for importance of meaningful technology integration in the educational settings within appropriate learning environments, supported by pedagogical and theoretical frameworks. Bers (2008a, 2010) recently suggested that robotics and programming can be integrated in developmentally appropriate ways in the educational practice.

Development of Knowledge and Skills: Cognitive and Non-Cognitive

Robotics has been connected to constructivism (Bauerle & Gallagher, 2003; Williams, Ma & Prejean, 2010). The teaching and learning theory that supports constructivism; highlights

the educational value of such exercises as the ones the integration of robotics in the educational practice can provide. Such exercises are based on the philosophy of “learning by constructing”, giving students the opportunity to develop interactive “thinking objects” (Bers et al., 2014; Kafai & Resnick, 1996; Papert, 1993 ; Harel, & Papert, 1991; Papert, 1986). Students get into the process of evaluating, changing, differentiating, re-designing, re-constructing and re-programming their objects (Puntambekar & Kolodner, 2005). The construction of such objects helps students to represent reality (Bers et al., 2014; Eteokleous, 2016; Kazakoff, & Bers, 2012, Kazakoff, & Bers, 2014). It is in this context, where students have an active role, they understand the connection between theory and practice, relating the abstract to the concrete, as well as relate what they learn within the classroom to reality and nature (Miglino, Lund, & Cardaci, 1999; Sullivan & Bers, 2015; Sullivan & Moriarty, 2009).

Within a constructivistic learning environment, students have the opportunity to manage their learning; they are free to discover, and decide on how to proceed. It promotes a student-centered environment where students through collaboration and social interaction have active role in the teaching and learning process. Along the same lines, the developmentally appropriate integration of technology is informed by Piaget’s ideas and the theory of constructionism and constructionist (Kazakoff, & Bers, 2014).

Research has shown that robotics integration in education promotes the development of various non-cognitive skills such as thinking skills such as application, synthesis, evaluation, problem solving, decision making, and scientific investigation (Bers et al. 2002; Bers et al., 2014; Chambers & Carbonaro, 2003; Eteokleous, 2016; Kazakoff, & Bers, 2012, Kazakoff, & Bers, 2014; Resnick, Berg, & Eisenberg, 2000). Besides the achievement of non-cognitive skills, when students are provided opportunities to become involved with robotics and programming, deeper and better understanding and engagement with STEM content

can be achieved (Gura, 2011). Along the same lines, the developmentally appropriate ways of robotics and programming integration can promote students cognitive skills development in STEM and beyond (Kazakoff, & Bers, 2012, Kazakoff, & Bers, 2014). Additionally, disciplines integration improve learning, not only among subject matters related to STEM. Finally, it is argued that when students take the role of programmers new skill and concepts are likely to be developed (Kazakoff, & Bers, 2012, Kazakoff, & Bers, 2014).

The Educational Robotics Curriculum

The Robotics Academy at Frederick University (Department of Education) (<http://akrob.frederick.ac.cy>, (<https://www.facebook.com/AkadimiaRompotikis>), a research and educational unit that aims to promote and conduct research in the area of robotics education, was launched in order to establish and stimulate robotics mainly to the Cypriot educational system and society. Specifically, it researches how to best integrate robotics in the educational system as a subject-matter, as well as a cognitive-learning tool within the teaching and learning process (employ robotics as a tool in order to achieve disciplinary learning objectives and the development of non-cognitive skills). The Academy offers courses using various robotics packages. The target audience is educators and students (all educational levels) and anyone interested in robotics (hobbyists and professionals).

The Robotics Academy developed an innovative curriculum for students and educators in all educational levels. The curriculum is constructed based on the philosophy *Robots- Partners in Learning: Examine, Explore and Discover through Construction and Programming*, integrating various theories and approaches. The educational robotics curriculum aims to develop participants' knowledge and skills in robotics (theory), in constructing various robotics models and in programming the robots. Various educational robotics packages and visual programming platforms are

used. The participants are engaged in hands-on, technology-based as well as unplugged activities related to robotics, based on the grounds of gamification, project, problem and inquiry based learning.

MAIN FOCUS OF THE ARTICLE

Research Methodology

A descriptive case study methodology was implemented (Cohen, Manion, & Morrison, 2008; Yin, 2003) collecting mainly qualitative data by using the following data collection methods:

- Student portfolios: Students' programming samples (coding), and robotic projects.
- Teacher artifacts: Lesson plans, exercises, handouts, teacher reflective journals completed after each course
- Classroom observations
- Student assessment exercises/ rubrics
- Teacher technology self-efficacy questionnaire (prior classroom interventions) (Kassotaki & Roussos, 2006)
- Teacher personal interviews (30 minutes each) prior and after robotics integration.

The teachers voluntarily participated in the study following announcement of the opportunity via email to their respective principals. The students and parents completed consent forms. In order to provide equal educational opportunities to schools and educators, emails were sent to rural and urban public schools in order to have students from different areas and socio-economic status.

Three of the schools are located in rural areas and five in urban areas. Overall, 8 teachers (aged 30-45 years old) and 169 students participated in the classroom interventions, 82 boys and 87 girls, aged 7-12 years old (from 2nd to 6th grade). The classroom interventions took place in public elementary schools, in different educational elementary levels, and disciplines, employing three

robotics educational packages: the Bee Bots, Lego WeDo, Lego Mindstorms NXT. The classroom interventions varied in regards to duration (5 to 11 lessons, 40 minutes each) due to the grade, the robotics packages used and the discipline areas. All of the interventions took place across various disciplines (See Table 1) and lasted from September 2013 to June 2015.

The Robotics Academy had the overall responsibility to professionally train the teachers and provide the required robotics packages and software. All teachers participated at the same professional development training provided by the Robotics Academy staff. Specifically, the teachers attended one-week intensive professional development training on educational robotics. The training focused on the following thematic units: robotics and educational robotics, philosophy of integration, learning theories related to robotics integration, added value, pedagogical and instructional strategies and approaches to robotics integration, robotics integration across disciplines. The teachers were also trained on how to use three different robotics packages (building and programming the robots).

The teachers were given the flexibility to choose disciplines and topics that they thought it would better fit to robotics integration. Along the same lines, the teachers decided upon the pedagogical and instructional strategies to employ for robotics integration. They needed though to ensure that robotics were integrated as cognitive-learning tools to support disciplinary knowledge and achieving disciplinary-related learning goals. The same approach adopted for the assessment. Each teacher was responsible to develop his/her own assessment based on the course nature and the learning goals set, to assess students' understanding, knowledge and skills development. The teachers were given templates to complete in regards to their reflective journals and lesson plans. A classroom observation sheet and an interview protocol were also developed. The author provided academic and educational support, guidance and help when requested.

Qualitative data collected through student portfolios, teacher artifacts, classroom observations, assessment exercises/rubrics and teachers' personal interviews. The MonoConc Pro 2.0. software was used and the qualitative data were analyzed implementing the continuous comparison of data approach (Maykut & Morehouse, 1994). The SPSS (v.19) was used for analyzing the quantitative data collected through the assessment exercises/rubrics and the teacher efficacy questionnaire.

Teachers' Profile

Overall, eight teachers participated in the study working in three rural and five urban schools. There were four male and four female teachers participated at the study, aged 30-42 years old). Four teachers had some experience in integrating robotics and programming. For all teachers technology self-efficacy was rated as medium to high. All of the teachers held master's degree in numerous fields (Environmental Education, Curriculum and Instruction, Educational Leadership, Special Education) and only three of them had master's degree in Educational Technology. Gender and teacher's self-efficacy (comfort with technology) did not reveal to influence robotics integration, however their educational backgrounds did. All teachers appeared to be open to challenges, not afraid to take risks and it seems that this is what is needed in order to implement new approaches and new learning tools.

Robotics and Programming Integration Across Disciplines

The classroom interventions took place across various disciplines besides STEM (Life Education, Arts, Environmental Education, Language and Linguistics, Geography, Health Education, English) (See Table 1). At the cases where the Lego Mindstorms NXT package was used, the teachers spent time within the Design and Technology discipline to teach students about the robotics package and programming platform.

The same happened in regards when the Lego WeDo package was used, however less time needed (only one period – 40 minutes). In only two cases there was no clear connection between robotics and programming and the disciplinary content delivered. Two teachers did not manage to meet the disciplinary learning objectives and successfully integrate robotics and programming within the educational practice. The two teachers have some similar characteristics and several factors contributed to this result. Both of them were very optimistic and decided to integrate robotics and programming in several disciplines, their master degree was not in educational technology and did not have prior experiences to robotics and programming integration. Even though their self-efficacy was rated medium, when they faced technical problems they tried to solve them by themselves, refusing to request technical support.

Assessment Exercises / Rubrics

The assessment exercises/ rubrics showed that in six classroom interventions the disciplinary objective were achieved and students managed to master disciplinary learning in a great degree. Teachers were very satisfied with the results and reported that the results were an encouraging factor to repeat this experience for their students and themselves. The five most enthusiastic ones declared their interest in further enhancing robotics and programming integrating experience with more robotic packages and in an increased frequency throughout the school year.

Teachers' Pedagogical and Instructional Strategies Implemented

The teachers implemented various pedagogical and instructional strategies to robotics and programming integration. The variations were due to grade, duration, the disciplines involved, robotics package used, teacher's educational background and prior experience to robotics and programming. Furthermore, the extent to which robotics

and programming were integrated varied as well among the eight teachers. Six of the teachers successfully managed to find ways (adopted the appropriate pedagogical and instructional strategies) in connecting the disciplines to robotics and programming. While examining the data collected the question to be answered was: *What does it mean when a teacher manage to integrate robotics and programming to disciplinary learning?* For the purposes of this study, robotics and programming are integrated as cognitive-learning tools when the students managed to connect the discipline concepts/ terms (theory) to robotics and programming (practice). When robotics and programming gave the opportunity to students to represent reality. For example, when in Safety Education the students programmed the robot to stop when the light turned red and to move when the light turned green. The particular unit aimed in developing students' knowledge and skills in regards to the rules and regulations that vehicles and pedestrians need to follow when driving/ walking in the streets.

Additionally, the four teachers that had prior experience to robotics and programming (minimum experience) designed and delivered more complicated exercises. Additionally, they developed graded difficulty robotics and programming exercises. Two of them hold a master's degree in Educational Technology. These two teachers managed to easily and effectively design the appropriate learning environment and adopted appropriate pedagogical and instructional strategies. The other two *experienced* teachers managed to unlock hidden possibilities of Bee Bots integration with 5th graders.

Teachers' Experiences, Reflections, Problems Faced and Lessons Learned

The teachers overall reported positive experiences to robotics and programming integration. They felt that it was valuable and beneficial to their teaching and learning and to students' learning.

They had the chance through this process to learn many new things. Two of them also reported that it is important to take risks in order to succeed. Three of the teachers faced difficulties in designing and delivering their courses in order to meet the disciplinary objectives. Overall, the teachers did not face any serious technical problems. Teachers managed to solve by themselves the ones that appeared and in few cases they asked for assistance from the school IT department. Teachers needed lots of preparation time to design and organize the lessons. Five of them of them discussed that they found it necessary to make adjustments while the lessons where evolved based on the experiences of the previous courses.

Other Factors

Additionally, various factors revealed to influence robotics and programming integration. Gender and class size are not included in the list. However, students' group synthesis appeared to be a factor that needs special attention. Mixed-gender groups worked much better together in constructing and building the robots, though female single-gendered groups worked better throughout the lessons' activities. Additionally, the choice of the appropriate robotics package in relation to students' age, discipline and learning objectives is an important aspect to consider. The selection of the appropriate robotics package highly influence the activities/exercises to be designed and delivered. Further, the results showed that there is no need to use a more sophisticated robotics package to young age students (i.e. Lego Mindstorms NXT to be used with 2nd graders). On the other hand, robotics packages for lower elementary grades students (i.e. Bee Bots) can be used for older elementary students when the appropriate pedagogical approaches and instructional activities are adopted..

Solutions and Recommendations

Overall, the study reveals robotics' effectiveness as a tool to develop students' knowledge and

skills, and achieve specific learning objectives across various disciplines, beyond STEM. It also highlights the need for teachers to be professionally trained, supported and guided. Difference in teachers' experiences and educational backgrounds are important to consider. Finally, the study suggests the value of adopting appropriate learning pedagogies and teaching approaches when robotics is integrated within classroom activities. The potential of robotics and programming was revealed in disciplines beyond STEM. The focus should be to engage teachers in using robotics and programming in their classrooms across disciplines

FUTURE RESEARCH DIRECTIONS

The paper has important educational and theoretical significance. It adds to the body of literature related to robotics integration within the teaching and learning practice and its impact on disciplinary learning objectives and skills development. The results of the study revealed the great potential of integrating robotics as a cognitive-learning tool to achieve cognitive skills in disciplines non-related to STEM. It sets the foundation to promote research in the field of educational robotics in order to further examine and define the appropriate learning pedagogies and teaching approaches to be employed. Additionally, it underlies the value of integrating robotics as an innovative form of teaching and learning to be applied in schools, in order to promote the development of skills beyond STEM.

CONCLUSION

The current analysis drawn from two years integration of educational robotics and programming across various disciplines. Overall, the study demonstrated the positive impact of robotics integration in mastering discipline learning in elementary educational level. The analysis revealed that in

six out of the eight classroom interventions, the students managed to master discipline learning and meet the learning objectives set by the teachers. The study also revealed the variations and commonalities among the eight teachers as well as the factors that may influence robotics integration. In general, it is examined how teachers integrated robotics, in which degree the integration was achieved and the learning goals met. The study also managed to capture their experiences, reflections, ongoing challenges, anticipated outcomes and achievements. The results and discussion take into consideration teacher digital literacy/ comfort level with technology, educational background, experiences, robotics packages used, class size, teacher age, gender, and experiences.

KEY TERMS AND DEFINITIONS

BeeBots: A colorful, easy-to-operate, and friendly little robot that can be used by students from the age of four to the age of ten, depending on the level of programming difficulty of each exercise.

Cognitive Skills: The skills developed that are related to specific disciplines. For example, for mathematics discipline, skills to be developed are: sequencing, calculation, multiplication; for physics discipline skills to be developed are: distances, angle. Newton’s law of motion.

Discipline Integration or Interdisciplinarity: It is the integration of various disciplines within the same unit, to examine one concept. The purpose is to relate/combine two or more disciplines into one exercise/ activity in achieving discipline learning objectives.

Educational Robotics: The use of robotics in the teaching and learning process (in the educational practice) as a subject matter and/or as a cognitive-learning tool to achieve disciplinary learning objectives.

Floor Mat: A paper or foam based mat (mainly located on the floor or high-table) which is separated in blocks of 15X15 centimeters. Each floor mat represents a specific theme/ concept and each block depicts different sub-theme/ sub-concept related to the overall theme/ concept. Each floor mat may have from 9 to 24 blocks (or even more!) Floor mats can be developed for various disciplines.

Lego Mindstorms NXT Robotics Package: An educational robotics package appropriate for secondary and higher education level students. The package contains a brick to be connected to the PC either through a wire or through Bluetooth, three motor sensors, touch sensor, ultrasonic sensor, sound sensor and light sensor. Additionally, it contains 431 building blocks, axles, gears, and cams. A visual programming software is also part of the package.

Lego WeDo Robotics Package: An educational robotics package appropriate for elementary

school students (7+ years old). There are two package available: the construction and the resource set. A visual programming software is also part of the package. The construction set includes a hub (to be connected to the PC), 3 different kinds of sensors (tilt, motor and distance sensors), 3 different sizes of axles, gears, cams, 158 colorful building blocks and other essential pieces to build the mini figure: the feet, hair and hut. The resource set includes additional building blocks, axles, gears and cams.

Non-Cognitive Skills: The skills developed that are not related to specific discipline however are considered to be important and necessary for students to develop in survive and succeed in the 21st century. Those are, but not limited to: problem solving, critical thinking, collaboration, communication, global citizenship, digital literacy, knowledge construction, creativity, innovation, self-directed learning.

Robotics Packages: There are various robotics packages that allow users/students to construct and program robots. These packages mainly contain bricks, wires, sensors and a visual programming software.

State of the Art and Key Design Challenges of Telesurgical Robotics

Sajid Nisar

National University of Science and Technology, Pakistan

Osman Hasan

National University of Science and Technology, Pakistan

INTRODUCTION

Telesurgical robotic systems allow surgeons to perform surgical operations from remote locations. It could be the same room where a surgical operation is being performed or a place somewhere else outside. It could be across two different countries or even cross-continental as demonstrated in “Operation Lindbergh, (Jacques Marescaux, 2002)” where surgeons performed laparoscopic cholecystectomy from New York, USA while the patient was at Strasbourg, France. Similarly, a telesurgery service was established in Ontario, Canada, between a teaching hospital and a rural community hospital located over 400 km away in 2003. It has been nearly twenty years since the emergence of telesurgical robotics in the operating room, but it has been only the last five years or so, that the potential of surgical robotics is being recognized by the surgical community as a whole. Now, it can be said with considerable confidence that robotic surgery has demonstrated numerous advantages over conventional surgery and it has revolutionized the operation theater (OT) as well as the surgical techniques.

Some prominent features of this technology are;

- More degrees-of-freedom for the surgical tool manipulation are available than the conventional one.
- Greater precision (even up to <10 micrometers) than the conventional surgical techniques where it is highly dependent of the

human hand resolution (100 micrometers typically).

- Less fatigue for surgeons, who now sit in an ergonomic console rather than being in an uncomfortable standing posture required by the conventional surgical procedures.
- Enhanced safety and increased patient trust in surgery by making use of comprehensive safety-critical features.

However, these advantages come at the expense of extremely high costs of these complex machines. It is yet to be determined when the benefits will outweigh the cost associated with these (Camarillo, 2004). Staggering capital and operational costs are a great challenge for the designers and engineers to bring down to a minimum possible level.

Moreover, telesurgical robotics is a multidisciplinary field and requires shared understanding among various professionals like medical doctors, engineers and computer scientists. Due to this diversity, there are various design objectives and meeting them altogether is a challenge in itself. A number of telesurgical robots have been developed so far with the objective of optimizing certain metrics and thus each one of these has its own advantages as well as shortcomings. The main scope of this chapter is to identify key design metrics for telesurgical robots and compare some of the notable existing telesurgical robotic systems accordingly. This information is expected to play a vital role while designing the next generation of telesurgical robots.

MAIN FOCUS OF THE ARTICLE

The main focus of this chapter is to provide a comprehensive survey about telesurgical robotics which can be equally beneficent to engineering and as well as medical professionals. After a brief background, a detailed discussion of various state-of-the-art telesurgical systems is provided. Key design approaches and challenges are identified and their solutions are recommended. A set of parameters that can be used to ascertain the usefulness of a telesurgical robot are discussed. These parameters not only allow one to choose the most suitable option among the existing systems but also could serve as guidelines for the development of next generation telesurgical systems. A separate section is dedicated for the future research directions followed by conclusions.

BACKGROUND

The stereotactic brain surgery by using Unimation PUMA 200 robot is considered the first robot assisted surgery (Kwong, 1988). In the beginning, there was a dearth of specialized robots custom-designed for medical surgeries. However, industrial robots had developed fully at that time and they were modified to cater the needs of surgery. Since then, many specialized robots have been designed to match the needs of surgical environments. A successful system requires concerted effort of engineers, medical practitioners, scientists and, to some extent, business professionals as well. To summarize the role and contributions, the medical professionals are the one who generally raise the need or a problem and engineers provide a doable solution. Surgeons act as its evaluators as they happen to be the directed customer-community as well. The business people provide a feasible way to commercialize the technology to make it commercially viable and meaningful. This scheme determines the dynamics of interaction amongst the contributing communities.

STATE-OF-THE-ART

The recent advancements in surgical robotics have led to an enormous usage in practice, making surgical robotics industry worth of more than \$0.5 billion per annum. For example, till 2009, da Vinci surgical system of Intuitive Surgical Inc. for laparoscopy was reportedly installed at more than 1,000 locations worldwide (Alterovitz & Desai, 2009). Moreover, it has been successfully used for thousands of surgical procedures globally. This success has increased the interest of researchers and investors, and therefore, a number of other systems have been built since then. According to one study, the worth of surgical robotic industry has been estimated to reach \$1.5 billion till 2018 (Global Industry Analysts, 2012).

Now, we describe some of the successful and well-researched telesurgical robots while highlighting their key features and capabilities.

Zeus Surgical System

The Automated Endoscopic System for Optimal Positioning (AESOP), a four DOF endoscopic manipulator, was developed by the Computer Motion Inc. AESOP was not a telesurgical system itself but it had been utilized as a building block for many other systems, including Zeus (Holt, 2004), developed by the merger of Computer Motion Inc. and Intuitive Surgical Inc. in 1995. It received the US Food and Drug Administration (FDA) approval in 2001.

Zeus comprised of three robotic arms attached to the OT bed. One robotic arm used the AESOP technology with a 3D high quality digital camera, while the other two were used for the surgical procedures. Zeus was the first telesurgical robot based on master-slave topology. The surgeons used a small master manipulator of 6 DOF to move the robotic arms (Holt, 2004). Zeus system is no more in production (Jyotsna Dwivedi, 2012) and has been superseded by the da Vinci surgical system.

da Vinci Surgical System

The da Vinci surgical system, also developed by Intuitive Surgical Inc., got its Food and Drug Administration (FDA) approval in year 2000 and became the first commercially used surgical robot. It had performed more than 360,000 procedures worldwide in 2011 alone (Blake Hannaford, 2013). With a net worth of approximately \$1.5 million (Yash, 2008), the da Vinci surgical system is one of the most expensive tools used by the surgeons today.

Like other existing telesurgical robotic systems, da Vinci is also based on the master-slave topology. It is mainly composed of a surgeon console, a patient-side cart, EndoWrist surgical instruments and a 3D vision system. Its surgeon console has two master manipulators and an incorporated 3D vision system. It can be used with three or four arms mounted over a trolley offering easy docking. Robotic arms use double-parallellogram mechanism to achieve remote center of motion. Specially designed metallic cables with high fatigue life are used for transmission. Surgical instruments are detachable during operation and need a replacement after a certain number of surgical operations, 10 as mentioned in subsequent portion of this chapter. This makes the running cost of the da Vinci surgical system quite higher and difficult to sustain for small and medium-sized medical organizations. The bigger footprint of system makes it difficult to transport and adjust in OT environment. However, the ergonomic ease and enhanced vision systems of da Vinci has been quite popular among the surgeons. The limited feedback has also been very useful during the medical procedures.

Raven Surgical System

Raven I and II are telesurgical systems developed by the BioRobotics Lab, University of Washington. Raven II is the latest and an improved version of Raven I. It has been presented as an open source system for collaborative research for advances in medical robotics (Blake Hannaford, 2013).

Main components of the Raven II include the patient-side (slave), the surgeon-side (master) and an integrating unit. Raven II manipulators are based on spherical mechanism which is relatively complex to actuate. Raven can be mounted on either side of the surgical site and up to four arms can be used in a single surgical field. It supports 4 DOF and removable surgical instruments during operation. Raven II uses Phantom Omni devices as its master manipulators. However, Phantom Omni are multipurpose devices and are not tailored for medical robots. These have certain limitations such as being not able to retain a particular posture freely, and thus, lacking the ergonomic ease for surgeons.

SOFIE Surgical System

“Surgical robot with force feedback” (SOFIE) is developed by the University of Technology (TU/e) Eindhoven. The system provides surgeons a compact layout with haptic (force) feedback. Based on a master-slave topology, it has specifically designed master manipulators for surgical maneuvers.

The Sofie system is mainly composed of two slave robotic arms mounted on a bed side, two master controllers incorporated with haptic feedback and software control and integration of master and slave. It uses customized master manipulators which provide considerable ergonomic ease. The biggest short coming of this system is bulky tool head. The tools are not detachable during a surgical procedure. The systems makes use of an ordinary vision system as well. Furthermore, to the best of our knowledge, it has not been tested in an OT environment yet.

Mirosurge Surgical System

MiroSurge is developed by the German Aerospace Center DLR for MIS and open surgery. The use of bimanual haptic force and the partial tactile feedback gives operator direct perception of the remote surgical field. It also gives surgeon the

flexibility to control instruments by optically tracked hand-held forceps (Tobergte, et al., 2011). Based on the master-slave topology, MiroSurge has its own master devices and it also has the ability of force reflection. It uses controlled RCM technique along with a robust control system. In case of a failure, robotic manipulators could lose RCM which is highly dangerous. However, it uses force-torque sensors which make it considerably safer during operation.

MiroSurge is mainly composed of two surgical arms with haptic feedback for holding instruments, one surgical arm with two endoscopic High Definition cameras that provide stereoscopic 3D image and a contact free interface as surgeon console. It provides a dedicated left and right handed control comprising of 7 DOF. Currently, MiroSurge uses bed-side mounting, which somewhat hinders its portability. It also requires specially customized OT bed for operation. However, the surgeon console is quite ergonomic and controlled RCM provides the flexibility of easy setup.

Al-Zahrawi Surgical System

Al-Zahrawi surgical robot is intended for MIS and is developed by National University of Sciences and Technology, Pakistan. The system is composed of master manipulator mounted over surgeon console, slave manipulator supported by a ground support trolley, instrument module and a control unit. Based on the planar parallelogram RCM kinematics, the system implements master-slave topology. Uniquely designed modular surgical tool wrist is interchangeable during operation. Furthermore, the distal end of the slave manipulator and tool wrist do not contain any circuitry and, therefore, are fully sterilizable (Hassan, 2014). The overall size and footprint of the system is relatively smaller and makes it suitable for MIS. However, it lacks haptic feedback.

KEY DESIGN APPROACHES AND CHALLENGES

Telesurgical robotics, being a multidisciplinary field, requires a comprehensive approach to design a successful system. Hence, it is imperative to figure out the key design approaches being used so far and their respective challenges. The above discussion about various robotic systems makes it clear that the following key design challenges are of prime importance for a robust telesurgical robotic system.

Manipulator Configuration

Selection of an appropriate configuration of a manipulator mainly depends on its application. For example, for fulfilling the large workspace requirements, as in the case of brain, thorax and abdomen surgery, series structures are preferable (Zhijiang, 2003). Similarly, parallel structures can be used for narrow, long and slender workspaces which may require more power to manipulate the end-effectors, as in the case of minimal invasive surgeries for retina, nose and ear. Configuration also determines the complexity of control and manufacturing. For example, series structures are generally difficult to control as compared to parallel structures. Moreover, actuator mounting and positioning becomes critical for series structures whereas in parallel structure it is relatively easier.

Remote Center of Motion

The remote center of motion (RCM) is a key requirement of minimal invasive techniques. Mechanisms are built such that there is no lateral or side-ways motion at the entry port of surgical tool. This entry port coincides with the RCM of manipulator to reduce the stress over adjacent tissues. A detailed study of 1-DoF remote center of motions is presented by (Guanghua Zong, 2008).

However, RCM in existing systems is primarily achieved using following two basic techniques.

1. Using Control Algorithms

In this technique, the RCM is achieved via control algorithms that govern the manipulator. It gives the flexibility to alter and can be adjusted on more than one points in the manipulator workspace. However, in case of a failure, there is always some risk of manipulator going rogue, which is highly undesirable. DLR Mirosurge makes use of this type of RCM. However, given the flexibility to change RCM position at any time makes system ideal for both open surgery and MIS. Whereas, the mechanism singularities encountered in such type of arrangements often need extensive research to deal with.

2. Using Remote Center of Motion Mechanisms

This technique uses the mechanical design of the manipulator to achieve the RCM. The mechanism is designed in such a way that the end-effector revolves around a single point. This approach is intrinsically safe and has been applied in most of the present telesurgical robotic systems like da Vinci, Sofie, Raven and Al-Zahrawi. But, systems based on such mechanisms usually have bigger motion envelop which has its own downsides. The fixed shape and form of the manipulator makes it impossible to change the position of the remote center of motion without moving the whole mechanism.

Miniaturization

The space and volume constraints always attach compulsion to a surgical system to be as compact as possible. The combined footprint of da Vinci surgical system, comprising of surgeon console, patient-cart and central unit is about 20 square feet as measured by authors at Qatar Hospital, Karachi, Pakistan. A similar observation of 22

square feet has been presented by (Eichel, 2005) as well. This makes the system bulkier and difficult to transport. Bigger size means more time and effort required to setup the system as well.

However, decreasing the overall size, weight and power required to actuate the system usually results in increased design complexity and short life-cycle of various key components. For example, the EndoWrists of da Vinci system are made compact, lighter and smaller which provides small space for cables to turn around. This decreases the fatigue life of cables and limits the number of usage of EndoWrist tool to 10 times at maximum. This, in turn, increases the overall operational cost of the system.

Tool Detachment

In one typical laparoscopic surgery, for example, more than five different surgical tools are used. This makes tool detachment an important requirement during a surgical procedure. The requirement of miniaturization impedes the process of detachment as it increases design complexity manifolds. In currently available systems, da Vinci and Al-Zahrawi surgical system provide tool detachment facility while performing a surgical procedure.

Power Transmission

A suitable power transmission scheme is key for the precision and accuracy of a surgical system. Currently available telesurgical systems mainly imply two types of actuation schemes;

1. Geared Actuation,
2. Cable Actuation.

Sofie and Mirosurge make use of the geared actuation scheme whereas da Vinci, Al-Zahrawi and Raven mainly make use of metallic cables. Gear actuation is considered more efficient and has longer life but the requirement of miniaturization makes it difficult to incorporate. Cable actuation scheme has the advantage of flexibility and ap-

plicability even to the complex designs but it has relatively shorter life. This also requires specially designed medical precision cables for the best performance and longer life. The slip factor is also critical for smooth and longer operation.

Backdrivability

Backdrivability is an important concept which defines the ability of a mechanism to be manually operable in backward direction. In case of a surgical robot, it means the possibility of the robot to be manually extracted out from the surgical site without doing any damage in case of a machine failure. Different kind of kinematic structures have different degree of backdrivability. Generally, manipulators having higher transmission ratios and active prismatic joints are considered non-backdrivable. Few of the existing surgical manipulators have backdrivability available for distal end degrees-of-freedom.

Haptics

Haptics (force and tactile feedback) provides a sense of touch to the remotely located surgeon and has long been a desirable feature in telesurgical robotic systems. Through haptics, the surgeon can feel and respond to a situation whether it's in training mode or operational mode. Early systems like Zeus did not support this feature. Incorporation of haptics makes the master controller design considerably difficult and, hence, requires a great amount of effort to fully evolve out yet. The technology for realistic haptic feedback is being actively researched upon.

Safety and Reliability

Since the birth of surgical robotics, safety and reliability has been the biggest challenge, given the safety-critical nature of applications. The fact that the da Vinci surgical system - only robotic system that made its way to the hospitals - is still under scrutiny by the FDA (Tanner,

2013) reflects the stringent criteria of safety and reliability. The seamless transmission of signals between master and slave robots during a surgical procedure is critical. It has been concluded by M. D. Fabrizio and others that a maximum time delay of 700 milliseconds is acceptable whereas, generally, a time delay of 300 milliseconds is considered completely safe. The reliability of teleoperation network is also crucial for a safe and reliable telesurgical robotic system. Frequent interruptions or failures result in loss of patient trust which needs to be avoided at all costs.

Multidisciplinary Nature

Multidisciplinary nature is a fascinating aspect of telesurgical robotics. However, for a relatively new field, there is a dearth of standard procedures which makes the collaboration among various communities challenging and less productive. Every community including engineering and medical has its own specific jargons, standards and communication protocols. Lack of standardization hinders an accurate assessment of needs and problems belonging to the area of one community by the other. This has been an impediment for many research systems to materialize as a successful commercial technology.

Solutions and Recommendations

Keeping the above discussed challenges in view, we now propose some solutions and recommendations for resolving the critical issues.

For miniaturization, the recent developments in the micro electrical mechanical systems (MEMS) augur a great deal of progress. Micro robots, containing microintegrated devices, are being developed which can work inside specific organs. Microtransmissions have been developed containing microgears as small as of a pollen grain (Camarillo, 2004). Despite of its great potential, use of MEMS in surgical robotics has not drawn full attention yet.

For tool detachment, a modular design approach is preferable. Surgical tools should be designed as a separate integrate-able module rather than a part of the manipulator. Doing so provides the flexibility of tool-change during a procedure. Such kind of technique is used in EndoWrist of the da Vinci surgical system. This technique can further be used to develop submodules comprising of tool's distal end. Such type of tools can be sterilized with a considerable ease and safety. Moreover, backdrivable manipulators can be designed by replacing active prismatic joints by revolute joints and balancing transmission ratios wherever possible.

To improve the haptic feedback, some out of the box solutions are needed as the conventional ways make the system design quite cumbersome. The use of various chemical and fluid sensors can provide some novel solutions. High fidelity force sensors can be used for this purpose as they have more force sensation even than that of the human hand (Camarillo, 2004).

To counter the challenges associated with multidisciplinary nature of the field, there is a serious need of some kind of standardization which can bring all related communities to a single page. This is difficult to achieve on an organizational level. However, efforts can be made to stimulate the surgical robotics community as whole to develop such kind of mechanism. The inclusion of relevant curriculum at school levels of all related communities could be a positive step in this direction.

Finally, the risk factors can be reduced and the robotic surgeries could be made further reliable by using more comprehensive reliability evaluation methods and having safety mechanisms. For example, rigorous analysis techniques like formal methods can be used to analyze the software and hardware components of a telesurgical robot. These techniques provide accurate analysis results at the cost of time and effort but their usage can be easily justified based on the safety-critical nature of telesurgical robots. Moreover, both hardware and software interlocks may be used to

avoid catastrophic complications. Better training mechanisms are also required to equip the surgeons with the skills that are essential to operate these sophisticated machines.

Moreover, the curriculum of most medical schools does not include hands-on experience with robotically assisted procedures these days. Hence, forcing surgeons to acquire these skills during their practice in a cluttered and haphazard manner. The students need to be trained in more innovative and productive ways. For this purpose, the virtual reality simulators can play a pivotal role.

FUTURE RESEARCH DIRECTIONS

About a decade ago, the maximum DOF offered by a telesurgical robotic manipulator were confined to 4-7. Whereas, now research is being carried out to increase this number to a certain level where surgeon can enjoy the liberties of open surgery. A further new trend is about the RCM mechanisms which could offer vital DOFs by virtue of the mechanism itself. These new mechanisms (Gijbels, 2014; Li, 2014, Nisar 2017) provide compact distal end which is highly desirable for MIS applications.

Tactile feedback is important for future surgical robots. The more recently developed da Vinci Si and Sofie system provide surgeons with limited force feedback functionality. Further research is being carried out to make these systems more realistic and user friendly. High speed data transmission and telecommunication protocols are the lynchpin of the future progress in telesurgical robotics. To reduce the time delays and ensure seamless transmission of signals it still requires effort to improve the communication and relevant hardware technologies. Reduced footprint and miniaturization is at the core of the future research efforts. The systems like Raven and Sofie are focused to have smaller motion envelopes.

Low cost surgical systems yet seem a distant dream. This can be established by the fact that, in 2004, the older version of da Vinci surgical system

with 03 arms had a cost of around \$1 million, and additional operational costs were about \$130,000 per annum. Later versions with 04 arms, and the da Vinci S, made available in 2006, approximately costs of \$1.33 million and \$1.53 million, respectively (Justin & Albani, 2007). Being the lone commercial telesurgical system so far, this shows the trend of prices going up with each new version. So, to lower the price and reduce the overall cost of a telesurgical system has great potential to be investigated in future.

Autonomous surgical robotic systems would be the ultimate surgical machines. Autonomous and semiautonomous robots are being envisaged as future robots to replace the surgeon. Autonomous suturing and knot-tying has already been attempted by Endobot (Hyosig. Kang, 2001). Similarly, autonomous knot-tying is tried by another robot called EndoPAR by (Hermann Mayer, 2004) as well. However, these ventures are just confined to suturing and knot-tying. Therefore, development of such surgical robots for conducting full surgeries still has a long way to go.

Use of Artificial Intelligence (AI) and 3D visualization techniques is another hot bed of research in surgical robotics. Neuromorphic engineering, genetic algorithms, and artificial evolution are some of the future directions of research regarding this aspect (Camarillo, 2004). 3D visualization of surgical field increases depth perception capabilities of surgeons while performing operations. 3D mapping, virtual construction of the surgical field can help surgeons to preplan and even rehearse their surgeries. This can greatly reduce chances of any mistakes or errors.

CONCLUSION

Last two decades have seen a phenomenal growth in telesurgical robotics and, therefore, brought a paradigm shift in the field of surgery. Now surgeons using robots have access to enhanced dexterity, control, precision, 3D vision systems,

and image and motion scaling during the surgeries while sitting back in an ergonomic console. Moreover, the robotic hands do not shake and there are less chances of errors. Smaller incisions, less blood loss and faster recovery promise telesurgical robotics a bright future. These robots are also paving paths for many interesting areas of research in medical surgery. For example, surgical robots have been used to do many successful kidney transplants of obese patients, which was classified as a very risky procedure earlier.

Despite enormous advantages, the usage of telesurgical robots in the OT is quite limited. The major reasons include high costs and the tough safety and reliability constraints. In order to develop more cost-effective and reliable systems, cooperation between engineers, computer scientists and surgeons is vital. This chapter provided a brief overview of the existing telesurgical robotic systems and the associated challenges and key design approaches in a non-technical language in order to provide a common ground for healthy discussions among the diverse communities. We identified the safety and reliability issues as the main bottle neck in this area and have proposed some methods for improving the state-of-the-art. We observe that surgeons' training need to be more intuitive. In terms of technological advancements, we see an increased incorporation of haptics and the introduction of more DOF in the next generation of telesurgical systems. Exploration of autonomous and semi-autonomous systems are the prime future research initiatives. The challenges of accuracy, precision and miniaturization are being confronted with great zeal whereas the issues related to reliability, cost and telecommunication still need to be considered.

KEY TERMS AND DEFINITIONS

Motion Envelope: A motion envelope is a virtual volume representing all positions which a mechanism, and its linkages, achieve during its complete range of motion.

Remote Center of Motion (RCM): A remote fixed point, with no physical revolute joint over there, around which a mechanism or part of it can rotate is called remote center of motion.

Workspace: Workspace or reachable space represents all those points which can be reached by the end effector of a robot.

Telesurgical Robotics and a Kinematic Perspective

INTRODUCTION

The advent of Minimally Invasive Surgery (MIS) in surgical theaters has revolutionized the centuries-old art of surgery for various surgical procedures. After rapidly gaining its momentum in 1990s, MIS offered huge benefits over the traditional open-surgery techniques. Details of which can be found in (Satava, 2004; Lanfranco, 2004; Holt, 2004; Taylor, 2006; Kuo C. H., 2009; Nisar, 2015). Along with its revolutionary advantages, MIS proved to be a tedious and cumbersome technique for surgeons. For safety and better efficacy, it requires well-trained and skillful surgeons to carry out the surgical procedures. When compared with open-surgery, MIS techniques adversely affect surgeons' ability of direct-sight, sense-of-touch, depth perception and kinesthetic feel. These issues, along with numerous others pose serious challenges to medical doctors and surgeons when performing MIS procedures.

Surgical robotics, primarily, emerged as a very effective solution to the above-mentioned problems and many other related issues. With the passage of time, these robots started taking the role of augmenters and led to the emergence of many innovative, safer, better and user-friendly features pertaining to various MIS procedures. This gave huge impetus to the ongoing research in this field and grabbed a lot of attention from researchers of many mutually varying fields of research. While industry has played an important role, it had been the academia that remained at the forefront of

the research in surgical robotics. Being in operation theaters for roughly more than two decades, surgical robots have demonstrated their potential towards the betterment of surgical procedures and general degree of efficacy (Taylor, 2006; Nisar, 2015). Enhanced precision, greater control over maneuvers, scalable movements and tremor-free tool motion with tactile feedback are some of the sublime features of today's surgical robots. Increased trust of surgeons, medical practitioners (Chitwood, 2001) and, even of the patients, on the use of robots for medical and surgical purposes is becoming a hallmark of this technology. With every new development, the overall size and weight of surgical robots is shrinking while the reliability and safety margins are expanding.

Behind every successful surgical robot, a number of technical and non-technical factors play an important role. For example, kinematics, dynamics, control and manufacturability are some of the technical aspects of a design. Kinematics - being the first and foremost manipulator design step - is considered as the lynchpin of performance for any surgical robot. It is a fundamental aspect of any mechanical design (Kuo C. H., 2012) and plays a decisive role in ascertaining its capabilities and viability vis-à-vis applications. A sound kinematic design is better posed to offer greater performance measures in terms of safety, reliability and surgical task-achievement (Kuo C. H., 2009). Kinematic design acts as a foundation block for the rest of surgical robotic system to be built over. A dismal kinematic design could severely limit the capa-

bilities of a robot for advanced features and vice versa. Therefore, it is important to understand the kinematic design approaches in practice so far and discuss their features and potential shortcomings.

A number of well-researched and peer-reviewed surgical robots in academia and industry for various minimally invasive surgical procedures have been proposed and many novel designs are being continuously investigated. Thus a survey of the kinematic aspects of these existing designs, giving an all-inclusive consideration, can play a vital role in understanding their pros and cons and thus improving performance of the new designs.

BACKGROUND

Most of the existing surgical robotic systems are telesurgical in nature, where the surgeon operates robotic tools remotely (Nisar, 2015). This remote location could be the same room as that of the patient or anywhere outside. Given the extensive focus on telesurgical systems, the terms ‘surgical robotics’ and ‘telesurgical robotics’ are sometimes implied in the latter’s sense despite of a certain distinction between the two.

A typical telesurgical robotic system constitutes of various subsystems, like master manipulator, slave manipulator, surgical tool with wrist, control unit and vision system. A system level explanation of a particular surgical robot is described at length in (Hassan, 2014). One key member, and a more interesting one from the robotics perspective, is the slave manipulator. Every manipulator is built upon some mechanism, which embodies the concept and ingenuity of its designer to achieve some specific task, for example, surgical tool movement in the case of surgery. This ability of a mechanism to achieve the design-objective in terms of links lengths and joint angles is mainly defined by the robot kinematics. Kinematics, being a study of the motion geometry of a mechanism and its bodies, provides understanding about the position of its members and change in their positions with respect to time

as the mechanism changes its posture. Kinematic design plays a fundamental role and is a crucial factor in terms of its ability to achieve a given task and the overall design robustness.

A key approach to describe telesurgical robots is to classify them based on their kinematic designs. As described earlier, kinematic design defines the basic shape and function of a mechanism and dictates the terms to achieve the design goal such as surgical movements. Therefore, it is important to consider the kinematic perspective of the existing surgical robot designs in order to get a broader and clear picture of the overall progress in the field.

Historically, industrial manipulators were the first to be modified and used for surgical applications (Satava, 2004). Later on, special designs and dedicated manipulators were proposed and implemented for surgical purposes. Most of the surgical applications and majority of the surgical robots are intended for the MIS procedures (Taylor, 2006; Kuo C. H., 2009; Nisar, 2015). Therefore, before examining the available kinematic designs, it is important to understand the operational concept of MIS and its kinematic requirements.

Concept of MIS

Minimally Invasive Surgery (MIS) involves long and slender surgical tools called laparoscopes. Surgeons insert these tools inside the patient body and get visual feedback from one of the tools having an endoscopic camera at the distal end. Generally, three or more such tools are inserted inside the patient body through small holes called as incisions (Howe, 1999). A device, called trocar is used to provide a safer passage to operate the surgical tools at the incision point without causing any damage to the neighboring tissues.

DoFs Requirement

A general MIS procedure requires 4 degrees-of-freedom (DoF) for tool manipulation at the point of incision. The open-close and tool tip movements are generally obtained through dedicated distal end

Figure 1. Typical tool setup in MIS

wrists and, thereby, do not play any significant role in the manipulator (slave) kinematics. The four DoFs required, referred here as primary MIS DoFs, are shown in Figure 1 (labeled as pitch, yaw, roll and translation).

Remote-Center-of-Motion

Figure 1 also demonstrates that the surgical tool is required to be virtually hinged around the incision point. It can translate inwards/outwards through the incision and can rotate along its center. This point is usually called as Remote-Center-of-Motion (RCM). Being a fundamental require-

ment for telesurgical robots, intended for MIS, it is defined as a point around which a mechanism or a part of a mechanism rotates around (Taylor, 2006; Nisar, 2015). The mechanism that achieves RCM is generally called an RCM mechanism (shown in Figure 2). When actuated for the pitch and yaw DoFs, its distal end remains virtually hinged around and rotates along the RCM point.

Workspace Requirements

It has been concluded through experimental observations (Lum M. J., 2006) that during a typical MIS process, 95 per cent motion of the surgical

Figure 2. A general remote center of motion mechanism

Figure 3. Workspace requirements for MIS

tool is confined in a 60 degree conic region, named as Dexterous Workspace (DWS). The remaining 5 per cent tool movements are contained in another conic region called as Extended Dexterous Workspace (EDWS), which is defined by the intersection of a 90 degrees cone with elliptical base and DWS, as shown in Figure 3. Dexterous Workspace and Extended Dexterous Workspace together define the required workspace for MIS (Lum M. J., 2006).

MAIN FOCUS OF THE ARTICLE

The main focus of this article is to present a general survey of the present day telesurgical robotics technology from a perspective of their kinematics. A number of prevalent kinematic structures in the state-of-the-art telesurgical robots are discussed and the factors shaping their kinematic design are analyzed. Based on that, advantages and potential shortcomings of these kinematic structures are highlighted which could be instrumental for engineers and designers to have a comprehensive understanding of the existing technology. Key design issues and challenges are summarized. To make future surgical robots more effective and useful, possible solutions and recommendations are made in a separate section. The last section gives a discussion about the future trends and possible ways to proceed forward for the telesurgical robotics in near future. The chapter deals with robotics for telesurgical applications, in particular. However,

the discussion and findings in many cases could be applicable to general surgical robotics as well.

PREVALENT KINEMATIC STRUCTURES

Detailed description of several notable surgical robotic systems, such as Zeus surgical robot, da Vinci surgical system, Raven, Sofie, DLR Miro-Surge and others, can be found in (Kuo C. H., 2009; Nisar, 2015). Here, we describe and discuss the kinematic structures which have been commonly used in existing surgical robotics research including the above systems.

Planar

Planar mechanisms have been one of the most widely used kinematic structures in surgical robotics (Li J. G., 2014). Given their advantages of planar motion, it is easier to place three or more manipulators around the surgical site and operate them simultaneously. Their motion envelop is generally compact (Nisar, 2015) and offer the flexibility of using redundant links to increase the mechanism stiffness. Such mechanisms generally offer higher safety features and better suitability for surgical purposes.

Parallelogram-based RCM mechanisms (Figure 2) are a typical example of planar RCM kinematic structures. Initially proposed by (Taylor et al., 1998) and later on developed in many

Figure 4. Depiction of a serial structure in MIS setup

different forms (U.S Patent No. 5,807,377, 1998; Bedem, 2010; Hassan, 2014), parallelogram mechanism has been the most popular choice in planar RCM mechanisms. The mechanism offers one DoF motion (pitch) and the other DoF (yaw) is obtained by tilting the whole mechanism along its base axis, as shown in Figure 2. The problem with these mechanisms is their limited number of DoFs offered by the mechanism itself. To achieve the translation and roll DoFs, external means are employed, which can have adverse effects on the performance of the manipulator (Gijbels, 2014; Li J. G., 2014, Nisar, 2017). A unique feature of such mechanisms is that they have a number of variants, which have the same function but are geometrically different. Thus, giving the flexibility of implementation in many different surgical application scenarios. Gear drives, cable-pulley schemes and synchronous belt-drives can be used to transmit power while keeping the actuators at the base of the mechanism. da Vinci surgical robot (Intuitive Surgical, 2015), Sofie surgical system (Bedem, 2010) and al-Zahrawi surgical manipulator (Hassan, 2014) make use of planar kinematic structures to achieve RCM.

Serial

Another popular kinematic structure found in surgical robots is of serial type. In a serial chain, tail of one link is connected with the head of the previous link and so on. Such kinematic chains are easier to design and solve for the mechanism singularities. Conventional algebraic and geometric approaches are often sufficient to solve the kinematics of these mechanisms. Serial chains

are usually fully-backdrivable which is a highly desirable feature for a surgical manipulator. The end link in these kinematic structures usually acts as the wrist of the surgical tool while the serial-chain is used to achieve the primary DoFs required for MIS. Lower joint stiffness and higher rate of error propagation are two typical problems encountered with serial chains. Moreover, serial structures need a careful consideration to design against gravitational instabilities. DLR Mirosurge (Hagn, 2010) and Raven (Lum M. J., 2009) are comprised of this kind of structures.

IsoCenters

Isocentric kinematic structures offer a more natural solution to the MIS needs. They consist of a pin-in-ring mechanism; having a ball and cylindrical joint at the center of the ring. The main idea behind such a mechanism is illustrated in Figure 5. The ball and cylindrical joint together offer the four primary DoFs required for MIS. Isocenters have been used in the Zeus Surgical Robot to achieve RCM (Kuo C. H., 2009). However, the mechanism could not gain much interest and is getting less and less attention in the recent years. One reason for this is the physical constraint at the incision point, which makes it difficult to coincide the RCM with the incision point. Also, the implementation of the ball and cylindrical joint at the same point is difficult to realize in a physical system.

Spherical

Spherical kinematic structures make use of spherical/circular arcs to achieve the pivoted motion at

Figure 5. Pin-in-ring arrangement in Isocenters

RCM. Like the planar structures, these are also an extension of serial chains but are spatial in nature. The circular members are designed in such a way that together they constitute a virtual sphere and the center of the sphere acts as the RCM point. The mechanism offers pitch and yaw DoFs implicitly while the translation and roll DoFs are achieved through external means. Among the notable systems, the Raven surgical robot (Rosen, 2010) uses this kind of a kinematic structure. Though easier to model and more intuitive for RCM applications, the problem with such mechanisms is their requirement of high-degree machining accuracy during fabrication. This makes them difficult to realize using conventional means, which adds to the overall cost of a surgical system. Figure 6 shows a spherical kinematic structure in an MIS application.

Continuum

Flexible manipulators have recently shown a great potential for surgical applications. In particular, they are being widely advocated for Single Access Port (SAP) surgeries. However, these snake-like structures are difficult to model and control. The computational cost is often higher for such mechanisms in practical situations. The repeatability and

Figure 6. Spherical kinematic structure with MIS DoFs

precision of such structures is difficult to maintain which also has been a major bottleneck of their practical utilization in MIS. Various methods and techniques exist to achieve snake-like motions. For example, use of cable-and-pulley and tendon-driven disks have been in practice for some time. More recently, memory-shaped alloys are being used to achieve the surgical DoFs needed for the MIS. Though not fully mature yet, flexible continuum manipulators have the potential to further revolutionize the field of surgery. Figure 7 shows a concept diagram of a flexible snake-like manipulator in an MIS setup.

Parallel/Spatial

Though common in many industrial applications, parallel structures are rarely found in surgical robotics. Generally consisting of spatial platforms, they achieve RCM by using one or more links moving in a controlled fashion. The surgical tool is usually mounted on the platform and the pitch, yaw and translation DoFs are achieved by virtue

Figure 7. A snake-like continuum structure in MIS setup

of the mechanism. Such mechanisms are usually easier to build but are difficult to model and control. Their kinematic analysis is relatively difficult and, in some cases, becomes computationally too expensive. Moreover, due to their spatial nature, they are not ideal for surgical setups where multiple manipulators are required to perform the surgical tasks in a confined space.

FACTORS SHAPING THE KINEMATICS

In this section, we discuss various key factors that affect the kinematic design of a mechanism:

1. Intended applications
 - a. MIS, being the major application, has greatly influenced the existing kinematic designs. The incision-point and conic-shape constraints of the required workspace have given rise to a whole family of remote center of motion (RCM) mechanisms.
2. Mode of operation
 - a. Systems intended for tele-operation mostly employ the master-slave topology. For easier mapping solutions, similar kinematic structures are used for both manipulators. Whereas, in the case of autonomous or semi-autonomous robots, slave manipulator kinematics provide the flexibility to be diverse and thus further extend its functionality.
3. Operational role
 - a. The robots that are designed for assistance (e.g. camera navigation, inspection) usually have simple kinematic design pertaining to the relatively simpler job at hand. For interventional manipulators, the structure is supposed to have extra DoFs due to the complicated nature of intended operations.
4. Operating environment
 - a. Indoor/outdoor: Indoor operations generally require a more compact motion envelop compared to the outdoor operations. On the contrary, outdoor operations require lighter and portable kinematic structures.
 - b. Underwater/space: Though only a few robots (Charles, 2009; Haidegger, 2008) are intended for such extreme environments, but the factors affecting kinematic design greatly differ in such applications. For example, underwater robots need to withstand extra torque and loads, thereby, requiring kinematics to substantiate the manipulator performance on these aspects.
5. Haptics
 - a. Haptics is becoming a necessity these days and many modern kinematic designs are supporting this feature. Incorporation of haptics influences

the overall size and imposes space constraints.

6. Control and Sensing
 - a. Being central to the robot performance, simple kinematics is preferred for easier control. Complex kinematic structures are usually less spacious to accommodate force, torque and many other kinds of sensors.

ISSUES AND DESIGN CHALLENGES

After highlighting the critical factors affecting the overall kinematic design, it is important to identify key issues and design challenges for surgical robots in this regard.

Mechanism Singularities

Mechanism singularities pose a serious bottleneck for many of the mechanism discussed above. Singularities represent configurations of the mechanism where it loses one or more of its DoFs. Mathematically, it is the configuration of a manipulator where its Jacobean matrix, which maps the joint velocities to the end-effector velocities, loses its rank. The mechanism renders itself useless for that particular DOF(s) in such a scenario and it becomes important to avoid any singularities falling within the workspace of the mechanism. A better kinematic design should be less prone to the kinematic singularities and, thus, more suitable for its surgical utility.

Novel RCM Mechanism

In formative years of surgical robotics, a number of new fundamental RCM mechanisms were proposed and many of these proved to be very successful for many surgical applications. However, recently the focus is shifting from innovative mechanical designs to robust control strategies.

Many researchers are trying to introduce tertiary features such as haptics and 3D-vision, and investigations for new RCM mechanisms are becoming very rare nowadays. Most of the kinematic structures used in recently reported surgical robots are based on older concepts and ideas. Surgical robotics have moved much further and we believe that new RCM mechanisms which could augment the shortcomings of the existing ones need to be designed and developed.

Haptics Incorporation

Most of the existing mechanisms and structures do not offer flexibility to incorporate extra features to achieve tactile or kinesthetic feedback. The surgical robots that provide limited forced feedback, like da Vinci and Sofie, are relatively bigger in size and have a larger footprint. One reason for this could be the fact that these kinematic designs were proposed when haptics was not considered as a prime requirement for a surgical system. With surgical technology getting mature and making in-roads towards difficult surgical procedures, haptics is becoming an essential part of a surgical robot now.

Realizability

The ability of a kinematic design to be manufacturable with conventional fabrication resources is a key factor for its success in the surgical market. Many mechanisms, such as spherical and isocentered approaches, are found to be achieving the surgical design objectives but are very difficult to realize as a physical system. Given the need of machining accuracy and fabrication precision, their physical development is costlier, and makes the overall system unaffordable for the health-care organizations. Easier realizability of planar parallelogram-based kinematic structures is the main reason behind their wide application range and high popularity.

Non-Modular Designs

Almost all of the existing kinematic designs are non-modular in nature. Modularity has particular advantages when it comes to surgical applications. It helps to make certain components of a manipulator sterilizable and, thus, reusable. Non-modular designs are usually expensive to maintain and inflexible to make modifications. In the surgical context, a modular design could offer the ease of change of surgical tools or faulty components and could make the robotic system useful and operational for longer periods of time.

Backdrivability

Backdrivability is the ability of a mechanism to be manually operable in backward direction. This is of prime importance when it comes to surgical manipulators. Given their safety-critical application, backdrivable mechanisms can be safely retracted out of the patient body in case of a machine failure without doing any damage to the neighboring tissues. Moreover, most of the revolute joints are usually backdrivable whereas active prismatic joints are considered as non-backdrivable. Many existing kinematic structures make use of active prismatic joints or cable-pulley schemes which have adverse effects on their overall backdrivability.

SOLUTIONS AND RECOMMENDATIONS

The typical planar RCM mechanisms, like the parallelogram-based ones, provide pitch DoF by virtue of the mechanism itself. The yaw DoF is easier to obtain as well. However, the remaining DoFs (tool translation and roll) have to be achieved through external means, such as cable-pulley schemes or actuators mounted on the distal end of the manipulator. This causes many other disadvantages, like increased inertia and vibrations at the distal end of the manipulator. To overcome

these issues, it is important to investigate new planar RCM mechanisms which could offer the translation DoF without using any external means. Recently, some researchers have proposed new mechanisms (Gijbels, 2014; Li J. G., 2014; Li J. Y., 2015, Nisar, 2017) on similar lines. Moreover, singularities can be avoided by altering the kinematics of the mechanism by using efficient and novel design and analysis techniques. Innovative control methods can be implemented to achieve stable and repeatable surgical movements.

Cable-driven systems have been the norm for flexible manipulators so far. Using more fatigue-resistant cables and frictionless joints can increase their utility and life span. Memory-shaped alloys could offer a better solution for the snake-like manipulators where relatively smaller movements are required. Recently, soft robotics has shown some progress in this regard and the results are also applicable to surgical robotics. For haptics, kinesthetic feedback could be given preference over tactile feedback. It has relatively small impact over the size and complexity of a design. Moreover, using compact and miniaturized sensors could further help in this regard.

Modular designs offer great benefits like sterilizable and reusable components. It could help to increase the product life cycle and reduce the operational cost of a surgical manipulator. On the other hand, it could introduce some issues like increased design complexity as well. However, it has the potential to outweigh its shortcomings. Furthermore, to enhance the backdrivability of a kinematic structure it is preferable to replace the active prismatic joints with revolute joints wherever possible. New mechanisms offering pitch, yaw and translation DoFs by virtue of the mechanism itself could be an amicable solution to the backdrivability problem.

In order to test and implement new designs, the use of rapid prototyping technologies and other novel manufacturing techniques could be instrumental. Kinematically robust mechanisms, but otherwise difficult to fabricate, could be realized with significant ease using such manufacturing

techniques. Such manufacturing methods could also be used to fabricate miniaturized components of the complex transmissions and, therefore, reduce the overall size of new robotic systems.

FUTURE RESEARCH DIRECTIONS

Recently, RCM mechanisms with additional degrees-of-freedom are getting an enormous attention. For example, traditional parallelogram mechanism offered the pitch DoF only. The new parallelogram based mechanisms offer pitch and translation DoFs inherently. This in turn helps to counter many adverse effects like higher inertia and energy requirements. Flexible and snake-like continuum kinematic structures are exhibiting great potential for the future surgical applications. Some other interesting directions of research in surgical robots include the investigation of methods for achieving flexible motion and the use of novel materials, like memory-shape alloys. Soft robotics is also a relatively new approach to design new kinematic structures which could bridge the gap between the traditional machine environment and human-machine interaction.

A more concerted effort is needed in order to achieve the primary MIS DoFs through manipulator mechanism without using any external means. Simple and easier to fabricate/assemble structures are highly preferable as well. Given the need of sterilization, future research needs to target kinematic structures with modular design.

CONCLUSION

This chapter presented an overview of the research in surgical robotics from perspective of kinematics. Various prevalent kinematic structures are described and their advantages and disadvantages are highlighted. It is evident from the discussion that simple and robust kinematic structures have shown more success than their complex and larger

counterparts. The factors affecting kinematics of a design have a significant impact on the design choices where most of the surgical robots either go for a spherical-serial kinematic structure or a parallelogram-based planar structure. Among the many available structures, parallelogram-based kinematic structures have been the most widely used ones and offer better prospects for MIS applications. Given the MIS requirements, most of the robots generate enough DoFs but not all of these DoFs are obtained through the slave kinematics itself. Almost every kinematic design needs to employ external means in order to fully achieve the primary MIS DoFs. Moreover, among the existing kinematic structures the ability of a mechanism to incorporate haptics varies largely. Future surgical robotic systems need to be compact, portable and more versatile in their modes of operation. Thus, we believe that there is a great need for new and innovative kinematic RCM structures which could offer all DoFs inclusively and have better support for haptics, modularity and miniaturization.

KEY TERMS AND DEFINITIONS

Minimally Invasive Surgery (MIS): MIS is a surgical technique in which surgical tools are inserted inside the patient body through small holes and thus allow the surgeon to operate using the video feedback from an endoscopic camera.

Robot Kinematics: Robot kinematics is the study of the position and movement of multi-degree of freedom kinematic chains that form the structure of a robotic manipulator.

Singular Configurations: Singularities are robot configurations where a manipulator loses one or more of its degrees-of-freedom and, therefore, cannot move in the corresponding direction(s).

Spatial Mechanism: Spatial mechanisms are essentially three-dimensional mechanisms such that one or more members of such a mechanism move in a plane different to others.

Workspace: Workspace or reachable space represents all those points that can be reached by the end effector of a robot.

Using Global Appearance Descriptors to Solve Topological Visual SLAM

INTRODUCTION

Nowadays, the use of mobile robots has extended to many different environments, where they have to move autonomously to fulfill an assigned task. With this aim, it is necessary that the robot builds a model of the environment and estimates its position using this model. These two problems are often faced simultaneously. This process is known as SLAM (Simultaneous Localization and Mapping) and is very common since when a robot begins moving in a previously unknown environment it must start generating a model from the scratch while it estimates its position simultaneously.

To carry out the SLAM process, the robot has to make use of the different sensors it may be equipped with (e.g. odometry, touch, laser, cameras, etc.). During the last years, the use of cameras has extended thanks to the amount of information they can capture from the environment and their relatively low cost. This work is focused on the use of computer vision.

When a vision sensor is used to solve the mapping and localization tasks, we must take into account that scenes contain a great quantity of information. This way, it is necessary to extract the most relevant information from the scenes as it will allow us to work with a lower

number of components. This problem can be approached from two points of view: local and global appearance methods. First, the methods based on local appearance consist in extracting and describing prominent landmarks or regions from the scenes. These methods typically need more computational time to build the map and estimate the position of the robot since it is necessary to extract the distinctive features from each image, describe them and make a complete comparison with the data stored in the map. Second, global-appearance methods describe each scene with a unique descriptor that contains information of the whole appearance. These methods tend to be computationally more efficient.

The SLAM problem can be approached from three different points of view: metric, topological and hybrid metric-topological SLAM. First, the metric approach consists in representing the position of some landmarks in the environment with geometric accuracy, with respect to a reference system. Using this approach, the position of the robot can be estimated with respect to this system. However, these methods often present a high computational cost. Second, the topological approach represents typically the environment as a graph, where the nodes represent prominent localizations (e.g. rooms) and links are the connectivity

relations between areas. These approaches offer a more compact representation that supposes a lower computational cost, but the localization process is inherently less accurate. At last, some researchers have started working on hybrid approaches that try to combine the advantages of the metric and the topological approaches.

The main objective of this work is to develop and test an algorithm to solve the SLAM problem using two sources of information: (a) the global appearance of omnidirectional images captured by a camera mounted on the mobile robot and (b) the robot internal odometry. We have decided to use a hybrid metric-topological approach to solve the SLAM problem.

BACKGROUND

The SLAM problem has been extensively studied. Moravec and Elfes (1985) developed one of the first works in this area. They build a metric map by means of wide-angle sonar range measurements and a probabilistic approach. Subsequently laser sensors were introduced to improve the accuracy and computational efficiency of the algorithms. For example, Thrun (2001) develops a SLAM algorithm in which a team of robots builds a map online using laser sensors and a Monte Carlo approach. Lately, the use of cameras in the field of mobile robotics has become widespread due to the numerous advantages they offer (passive sensors, low cost, large amount of information, low power consumption, etc.). Many authors have studied the SLAM problem both using local features (Gil et al., 2010; Valiente et al., 2015) or global appearance (Paya et al., 2014; Berenguer et al. 2015).

The main problem that local features present is the high computational cost of the necessary processes. As a feasible alternative, the use of topological approaches is a field of great interest in the construction of maps by means of the global appearance of visual information, due to the numerous advantages it presents in terms of

simplicity and computational cost. For example, Menegatti et al. (2004) carried out a study on robot navigation using the omnidirectional visual information captured from the environment, by using a global appearance descriptor.

Cameras have been used both to solve the SLAM problem metrically, topologically and in a hybrid way. For example, Guerra et al. (2014) and Gil et al. (2010) present two metric visual SLAM approaches using respectively a monocular and a stereo-camera and SURF features. On the other hand, Lui et al. (2012) develop a purely vision-based topological approach that builds an incremental model based on Haar Wavelet and Werner et al. (2009) carried out a task of topological SLAM using vision-based techniques and global appearance. They also make use of omnidirectional images, and furthermore they propose a Bayesian approach that combines the odometry information of the robot with the visual information to improve the accuracy. At last, Tully et al. (2012) develop a unified filtering framework for hybrid SLAM.

In this work we present a comparison of three global appearance descriptors in a process of robotic mapping, using a hybrid metric-topological SLAM.

APPEARANCE-BASED SLAM

In this work, we develop a new approach to hybrid SLAM, trying to obtain the advantages of each method. On the one hand, the topological representation permits building a global compact representation of the environment that permits a quick localization. On the other hand, the metric representation makes use of the information provided by the topological method to detect loop closures, so that it is possible to correct the possible errors in the position of the robot. In both cases, the global appearance of the omnidirectional scenes captured by the sensor mounted on the robot is used to create the model and localize

the robot. The next two subsections give details on the topological and the metrical approaches of the algorithm.

Constructing a Topological Map

In the global appearance approach, each scene is described by means of a unique descriptor that contains information on the whole appearance. This way, it is necessary to define first a method to obtain a descriptor per scene. This descriptor should retain the information in a compact and efficient manner and it must be computed quickly. In this work we make use of and compare three different and well known global appearance descriptors: Fourier Signature (FS) (Payá et al., 2010), the gist of the scene (Siagian and Itti, 2007) and the Histogram of Oriented Gradients (HOG) (Amorós et al., 2010).

In this case, the environment is represented through a graph where (a) each node represents an area of the environment and contains one or several images with similar visual appearance and (b) each edge represents the connectivity relationships between the nodes, i.e. the possibility to navigate from one node to another (Romero et al., 2010). Since each node may contain several images, a representative image per node is computed. We define the similarity $S(i, j)$ between two images I_i and I_j that belong to the same node with this expression:

$$S(d_i, d_j) = \frac{1}{\sum_{m=0}^M \sum_{n=0}^N (d_i(m, n) - d_j(m, n))^2} \quad (1)$$

Where $d_i(m, n)$ represents the descriptor of the panoramic image I_i . In general, the descriptor is a matrix of size $M \times N$. The distance criterion we use is the Euclidean distance, which is the term in the denominator. Then, the closer the images are, the smaller the distance and the higher the similarity $S(d_i, d_j)$. Once we have

computed the similarity between every two images in the node, we use the following equations to compute the most representative image:

$$\begin{aligned} N_R &= \max_{i \in P} \left[\min_{j \in P, j \neq i} (S(d_i, d_j)) \right] \\ R &= \arg \max_{i \in P} \left[\min_{j \in P, j \neq i} (S(d_i, d_j)) \right] \end{aligned} \quad (2)$$

Where P represents the set of nodes in the graph and R is the image that best represents the node.

Then, to build the topological map we use the following algorithm. Let's suppose the robot captures a new image I_k and this information has to be added to the topological map.

1. The descriptor d_k of the image is obtained and compared with the descriptor of the image that represents the current node R_c . If the similarity $S(d_k, R_c)$ is over certain threshold Th_{min} , it is added to the current node, and the node representative is re-calculated.
2. If the similarity $S(d_k, R_c)$ does not exceed the threshold Th_{min} , d_k is compared with the node representatives of all the neighbor nodes to the current one. The node with the higher similarity $S(d_k, R_{nei})$ is chosen. Then, if this new similarity exceeds the threshold, the current image is added to that adjacent node, and the node representative is re-calculated including the information of the new descriptor.
3. In the case that the similarity $S(d_k, R_{nei})$ does not exceed the threshold, the current image descriptor is compared with the representative descriptor of the rest of the nodes. If the similarity exceeds the threshold in any case, it is added to that node, and the node representative is re-calculated.
4. If no match is found, a new node is added to the system, so an edge between the new

node and the previous one is added too (i.e. they have become neighbor nodes). The new node includes the current image, which is also the node representative until a new image arrives, when this representative will be updated.

Constructing a Metric Map

The metric map is built using a visual SLAM approach based in Payá et al. (2010). We combine a Monte-Carlo Localization (MCL) algorithm with a landmark estimation process. The robot decides when its current location is included as a metric map landmark. The main improvements over previous work mainly lie in the combination of a mapping process and a localization process simultaneously, combining a topological method with a metric method.

In a MCL problem, the aim is the estimation of the robot's pose $x_{t+1} = (x, y, \theta)$ at time instant $t + 1$ using a set of measurements $z_{1:t+1} = \{z_1, z_2, \dots, z_{t+1}\}$ from the environment and the movements $u_{1:t+1} = \{u_1, u_2, \dots, u_{t+1}\}$ of the robot. The probability density function $p(x_{t+1} | z_{1:t+1}, u_{1:t+1})$ is represented by a set of M random samples $x_{t+1} = x_{t+1}^i$, $i = 1, \dots, M$ extracted from it (particles), where each particle can be understood as a hypothesis of the true state of the robot $x_{t+1}^i = (x^i, y^i, \theta^i)$. Each particle has a weight associated that determines the importance of the particle. The set of particles defines a discrete probability function that approximates the continuous belief. The original MCL algorithm consists of three main phases: (1) *Prediction phase*, in which a set of particles $\bar{\mathcal{X}}_{t+1}$ is generated based on the set of particles $\mathcal{X}_t$ and a control signal u_{t+1} ; (2) *Update phase*, in which the weight ω_{t+1}^i of each particle in the set $\bar{\mathcal{X}}_{t+1}$ is computed using the observation z_{t+1} ; and (3) *Resampling phase*, in which the resulting set $\mathcal{X}_{t+1}$ is computed by

resampling with replacement from the set $\bar{\mathcal{X}}_{t+1}$, where the probability of resampling each particle is proportional to its importance weight ω_{t+1}^i , in accordance with the literature on the SIR algorithm (Sampling Importance Resampling). Finally, the set $\mathcal{X}_{t+1}$ represents the distribution $p(x_{t+1} | z_{1:t+1}, u_{1:t+1})$.

In this work, since the objective is building a map of the environment while the position of the robot is computed (SLAM), the experiment starts without a map of the environment. Taking into account this consideration, the initial set of samples is drawn from a narrow Gaussian centered at the initial point $(x, y) = (0, 0)$. At the start of the experiment, the first map landmark (l_0) corresponds with the first pose of the robot x_0 and when the robot moves and captures a new image, the set of particles of the initial pose also moves adding some error to the movement of each particle, taking into account the movements $u_{1:t+1} = \{u_1, u_2, \dots, u_{t+1}\}$ of the robot. Moreover, the topological algorithm computes the representative pose of the node every time a new image is added, and it will appear on the metric map as the set of particles that represents the metric localization of the node. This way, each representative pose of the topological map has one metric map landmark (l_i) associated. So, although we compute each set of particles that represents each movement of the robot, we only add to the metric map the set of particles that represents the node. On the other hand, our MCL algorithm differs with respect to the traditional MCL algorithm in that we do not carry out an update and resampling process in each movement of the robot but only when the topological algorithm detects a loop closure, even though we perform a prediction phase at each movement of the robot.

When the topological algorithm detects a loop closure, an update and resampling process is activated. To compute the weight of each particle ω_{t+1}^i we use as input both, the metric information

Figure 1. Robot used to develop the SLAM experiments, catadioptric vision sensor and sample omnidirectional and panoramic images

(odometry) and the visual information (global image descriptor) through the following equation:

$$\omega_{t+1}^i = e^{-v_i \mathbf{f}_i^{-1} v_i^T} \cdot e^{-h_j \mathbf{f}_i^{-1} h_j^T} \quad (3)$$

where v_i represents the difference between the position of the landmark l_j and the position (x_i, y_i) of each particle i ($v_i = (l_x^j, l_y^j) - (x_i, y_i)$), $\mathbf{f}_i$ is a diagonal matrix $\mathbf{f}_i = \begin{bmatrix} \sigma_i^2 & 0 \\ 0 & \sigma_i^2 \end{bmatrix}$ where σ_i^2 has been chosen in order to minimize the error in the localization of the robot. On the other hand, $h = |d_j - d_i|$ is the difference between the appearance descriptor associated to the current observed image and the descriptor associated to the landmark l_j . Once the weight of each particle has been computed, the resulting set $\mathcal{X}_{t+1}$ is computed by resampling with replacement from the set $\bar{\mathcal{X}}_{t+1}$, where the probability of resampling each particle is proportional to its importance weight ω_{t+1}^i .

RESULTS AND DISCUSSION

With the objective of evaluating our SLAM algorithm, we carry out a realistic experiment with a

mobile robot in an indoor environment. The robot was manned to travel a specified route into the environment, so that several loop closures occur and it captured a complete set of images. The ground truth is computed from the data collected with a laser. Figure 1 shows the mobile robot used, the catadioptric vision sensor mounted on the robot and two sample images: an omnidirectional scene and its panoramic version. Figure 2 shows a bird eye's view of the environment where the experiments were developed and figure 3 shows some sample panoramic scenes captured in this environment.

Based on previous work (Payá et al., 2010) and to evaluate our method, we have decided to use the Procrustes analysis. It provides us with a measure of how similar is the layout of the landmarks after the SLAM process, comparing to the real layout. As a result of this process we obtain a parameter $\mu \in [0, 1]$ (shape difference), where μ is a measure of the shape correspondence between the sets of points A and B , so that the lower is μ , the more similar are A and B .

Figure 4 shows an example of metric map built after an experiment using the FS, 32 components per row and a number of particles equal to 200. In this figure, the particles that represent the position of the landmarks are plotted as green points and the resulting positions are represented with blue crosses. The internal odometry is plotted as a blue

Figure 2. Bird's eye view of the environment where the experiments have been carried out. The green dots are the positions where the robot captures a new image to be included in the model and the blue point is both the beginning and the end point of the route.

Figure 3. Some examples of panoramic images captured by the robot in the environment

line. Finally, the ground truth is represented with a black line. The ground truth is shown only for comparative effects, but it is not considered in the SLAM algorithm.

According to fig. 4, the particles' dispersion of each landmark grows when the robot moves from the initial position until the robot detects a loop closure. At this moment, the dispersion of the samples decreases due to the fact that the algorithm carries out a resampling of these samples. It can be observed that the map obtained by means of our algorithm is considerably more accurate than the map obtained through the internal odometry.

Once proved that the algorithm works with a specific configuration, a set of experiments has been designed to test the performance of the hybrid algorithm when the three different appearance-based descriptors are considered (FS, GIST and HOG). The influence of the number of components of each descriptor is tested, since this is an important parameter that may have an effect both in the accuracy of the process and in the computational cost.

On the one hand, the μ factor is used to evaluate the accuracy of the resulting metric map and on the other, the step time needed by the al-

Figure 4. Metric map built with the hybrid algorithm (blue crosses) compared to the map build from the odometry data (blue line) and the ground truth (black line). The descriptor is the FS with 32 components per row and 200 particles in the MCL algorithm.

gorithm is used to evaluate the computational feasibility (ability to work in real time). In all cases, the robot odometry is used as the input of the prediction phase in the MCL algorithm.

In Figure 5 we can see the μ factor and the step time needed by the algorithm, depending on the size of the descriptor. We have performed several experiments using the three descriptors (separately) and a number of particles equal to 200. We have chosen this number of particles as, in general, it offers a good accuracy with a relatively low computational cost.

As far as the size of each descriptor is concerned (a) in the case of FS we have to decide the number of components per row to store, (b) in the case of *gist*, the size of the mask used to calculate the descriptor can be configured, what has an effect on the size of the descriptor and (c) in the case of HOG, it is possible to modify the size of the descriptor by means of changing the size of the window used to compute the descriptor (Payá et al., 2014).

In general, fig. 5 shows that in the case of FS and *gist*, the accuracy is influenced by the size of the descriptor more than in the case of HOG. However, in general, we can say that the three methods present a good accuracy, even in the worst case. The μ factor is lower than 0.0075 in all the cases. We must take into account that the μ factor we get by using only the internal odometry without our algorithm is around 0.1421. With respect to the time t , FS clearly improves the other two descriptors. Anyway, with all three descriptors it is possible to work in real time since the times obtained are under 0.25 sec per iteration.

We have tested also the influence of the number of particles in the accuracy and computational cost, and the results have shown that the accuracy grows as the number of particles does until this number is equal to 200. From this number, the accuracy remains constant but the computational cost keeps on growing. This way, the optimal number of particles in all cases is around 200 particles.

Figure 5. Shape difference μ (left) and step time of the algorithm (right) versus the number of components of the descriptor. The FS, gist and HOG descriptors are evaluated.

FUTURE RESEARCH DIRECTIONS

The algorithm we have presented constitutes a promising starting point for the implementation of an accurate and efficient hybrid SLAM algorithm using the global appearance of visual information.

Currently, we are working in the improvement of this algorithm from several points of view. First, we are extending the algorithm to larger and dynamic environments including outdoors scenes. Second, we are considering the presence of some typical situations that usually come out when visual information is used: visual aliasing, occlusions (due to the presence of people moving), noise in the scenes and changing lighting conditions in the environment. We are evaluating new global-appearance descriptors and their ability to cope with these situations. At last, we are considering to include a multi-hypothesis framework that keeps some map hypothesis every time a loop closure is detected and that chooses among these hypothesis when it has enough information.

CONCLUSION

In this work, a hybrid metric-topological SLAM algorithm has been proposed and evaluated. The mapping and localization processes are solved

using the panoramic images captured by a catadioptric system mounted on the robot and three global appearance descriptors have been used: Fourier Signature, *gist* and Histogram of Oriented Gradients. This way, the contribution of the work is twofold: a new efficient SLAM algorithm is proposed and tested and several descriptors are evaluated and optimized. Thanks to this framework, compact maps of the environment can be obtained using only the odometry and visual information.

The experiments have been developed in an unstructured indoors environment where a set of real images have been captured. Both the size of the descriptors and the number of particles in the MCL algorithm have been evaluated and optimized to obtain an accurate map with a feasible computational cost. The use of several description methods proves that our algorithm is generalizable to any other image descriptor, including local descriptors.

KEY TERMS AND DEFINITIONS

Appearance Descriptor: It is a descriptor of an image that represents the global information of the same without extracting landmarks.

Gist: It is the meaning of a scene, or in other words, the spatial envelope of the scene.

Localization: It is the estimation of the position of an autonomous agent in a given map.

Mapping: It is the creation of an internal representation of any given environment.

Metrical Map: It is a representation of the environment through geometrical information with certain accuracy.

Mobile Robot: It is an autonomous vehicle that is capable of movement in any given environment.

Omnidirectional Vision: It is a vision system that is capable of capturing all the information surrounding the system with a single image (360°).

Probabilistic Localization: It is a localization task, where the information of all previous robot locations is used to estimate its current location.

SLAM: It is the process of building a map of an environment while simultaneously the localization of the agent that compute the map is estimated.

Topological Map: It is a representation of the environment by means of a list of locations within a graph with connectivity relationships between them.

INTRODUCTION

General perspective of the chapter is focused on the use of big data and intelligence in the field of information technology. Information technology (IT) supports the majority of the realized activities. The press is focused on time and quality. There are also competitions, customer preferences and downward pressure on prices and costs. In this situation, new products and services have to address both existing and new customers. Such innovations actively use information technology and available information from the Internet. Good and bad advice, experiences or requests are immediately available for everyone via successful story. (Concessao, 2016) The behavior of individuals in a global information society reveals similarities with regard to the collective behavior of animals in nature. Swarm intelligence provides inspiration for various fields such as economics, biology and also computer science.

The global information society creates data in various formats and data is stored in many sources. Data (big data) is everywhere around us. The well-known databases (Barbucha et al., 2015) are default data source, but there are many other sources such as the Internet, e-mails, chats, and also personal notes in PDF or text files. The volume of data is as large as the ocean or the universe. Users of information technology swim in the data without lifebuoys in all companies and organizations. Everyone wishes to get knowledge immediately in the needed format, but knowledge is not data. There are difficulties that cause ambiguous tasks, unrealistic expectations, faulty data or inadequate

procedures and processes. The special problems create a large volume of available data.

The objective of interest is native support of sustainable development based on big data and intelligence in the field of information technology. (Acharjya et al., 2015) In this situation, there is a spectrum of well-known approaches and the fields that are oriented on big data and intelligence such as artificial intelligence, business intelligence, competitive intelligence, customer intelligence, swarm intelligence and also computational intelligence. At first glance, working with data must use all suitable approaches for correct data analysis with respect to sustainable development. Sustainable development is important for supporting society's continuous development without crises. (World Development Report, 2015) The question is "How can be solved existing problems responsibly?" The easy way is to depend on governments or luck. Another way is to merge power of mankind based on cooperation and communication. In this situation, big data brings good results.

BACKGROUND

Working with big data requires optimal IT support, skills of IT users, and more predictive analytics. Sense and simplicity are in the forefront. Interest is focused on true story formation. For these goals, there is computational intelligence bringing IT power to problem solution. The basic step is correct problem formulation in a complex view. CPU speed, memory size, disk volume, and network connection are not critical elements. Information

technology has enough resources to work with big data. (Information Technology Market Reports, 2015) The question is to find the best data for the required analysis and to create a suitable story for the given reality. The main role of computational intelligence must be focused on helping with data analysis and predicting further development to break unexpected conditions in society. (Covington, 2016) Market competition creates other hard requests on realized activities, computers and their software, and also IT users. We need a solution that is better, faster, more user-friendly, more complex, and more predictive.

Regardless on the wide spectrum of hardware, software, available methods and verified methodologies, there are big data projects that end with mistakes. There is contradiction between expectations and reality. IT users rely on information technology as a unique tool supporting realized tasks and processes for solving existing problems, but they are often disappointed over achieved results. IT users often must say “It doesn’t work.” An active solution takes inspiration from nature, specifically swarm intelligence with links to business intelligence. In many cases, foundation work is simulation. The benefit is easy creation and modification of simulations without demands on finance, material, or human resources.

MAIN FOCUS ON EXISTING CONTRAST

Big Data and Controversies

IT product development is perceived with a wide spectrum of conditions and preferences. Optimal IT implementation must be evaluated based on the available IT product, technology issues, data difficulties, company philosophy, employment approach, motivation, the aims and concept, management support, end users, the learning process, security of application, measurement and evaluation. The perception of IT implementation

is a difficult process with a number of relationships. This volume information is beyond human capacity and a suitable arrangement is needed.

For optimal implementation, the verified methods and system architectures are defined (Crawley et al., 2015), but there are doubts about disproportionate demands on IT users, implementation teams, human resources, finances and time, or societal stability. From a long-term perspective of existing controversies, big data will bigger and bigger, and the pressure on reducing costs for resources will continue to be greater and greater. The frequently used keywords show the rapidly expanding sphere of interest in the area of big data in detail: Analytics - 4 380, Big Data – 4 330, Business Intelligence – 2 550, Data Architect - 911, Data Mining - 2 080, Data Science – 4 370, Data Warehouse - 408, Database – 1 460, Excel – 3 800, Hadoop – 2 410, IoT (Internet of Things) – 1 800, Operations Research - 513, Predictive Modeling - 898, Python – 1 130, SQL - 945, Statistician – 1 090, Visualization – 2 620. (Graville, 2013 - 2015; Big Data Science on twitter, 2015)

Controversies also bring absence public of optimal software implementations. Many surveys show an existing disillusionment from results based on processes with data and information. (Gartner Newsroom, 2015) The natural question is “How do data, information, and knowledge help with difficulties in the global society?” Big data is able to derive various relations about the actual reality (useful as well as useless) based on optimal visualization. (Clark, 2014) The global information society and their governments need more. (Simon, 2014) For everyone, there are important changes:

- The exchange of goods and services, data and information.
- The dependence on information technology in all activities.
- The perception of individuals and collective behavior like people themselves.
- The rhythm of life of modern civilization.

But it is not all. Human behavior is strongly affected by the social networks in communities. (Top 15 Most Popular Social Networking Sites, 2015) The default characteristic of decision-making is a requirement on time and quality. Collective experience and thinking with models has a positive influence. (World Development Report, 2015) This variability is important for everyday activities in such a dynamic and rapid society. For the global information society, these changes, as well as information technology, support controversies that are oriented around global challenges. (Rischard, 2002) Available spectrum of IT products with needed designs, simulations and methods create sufficient space for optimal software implementation. (Top 27 Free Data Analysis Software, 2015) With regards to actual conditions, managers, business owners and IT users have selected an optimal approach for use of suitable software. There are difficulties, unfortunately.

Big Data and Intelligence

Computational intelligence often uses verified techniques as neural networks, fuzzy systems, hybrid neuro-fuzzy approaches, or genetic algorithms. (Jain et al., 2014) These approaches are suitable for creating simulation via available tools and applications. The issue is their complexity and variability. Ongoing changes are very dynamic and they occur unexpectedly. Answers to these changes must be realized in very short time. (Zobaa & Vaccaro, 2015) These answers need easy manipulation and instant access to variable support. A little extra time is good to have for an optimal reaction to existing reality. Good prediction may give extra time for adaptation, but the question is about the adopted strategy for predictions and algorithm evolution; therefore, the new challenge is connecting computational intelligence with swarm intelligence, business intelligence, and data science for true story creation based on big data in practice. (Marr, 2016)

Visualization, selection of optimal data, and dimension reduction may help, but it is not easy in today's modern and complex world. (Dzemyda et al., 2014) Visualization brings many graphs in various formats, but which one of them is appropriate and how do we derive the needed knowledge? Selection of optimal data is also problematic with regards to dynamic changes of actual conditions and needs. The challenge is working with data and other sources as with mirrors to human behavior that is similar to animal and swarm intelligence. This mirror of future uses all intelligence systems that may help. Computational intelligence, business intelligence, and swarm intelligence play key roles. The focus is oriented on simulations that cooperate with humans in many areas to find all interesting solutions automatically.

A considerable volume of work is well-manageable in a team, but many IT users prefer instant solutions and independent work in an intuitive interface with examples. (Matei et al., 2015) It is also the reason that IT users rather prefer default MS Excel and available contingency tables and they do not use other software for future prediction. This is a fatal mistake. They voluntarily give up benefits from big data and other intelligences. (Mohanty et al., 2015) Information technology offers processes for the analysis of accessible and interesting links in existing data sources. It is possible to target marketing campaigns to individual customers not only based on their shopping behavior, but behavior on the website or social networking sites.

SOLUTIONS AND RECOMMENDATIONS

This contrast leads to new solutions, attractive innovations, and needed global cooperation. In many cases, nature is, and will be, an inspiration for new products and approaches in the IT field.

Optimal work with data and information is complex. It is not a pile of data, information and

knowledge in a vacuum. Similarly as human brain maps (Lewis, 2015), all relationships must be respected together with reflecting the actual reality. (Mayer-Schönberger & Cukier, 2014) The starting point is defined by a division topic on a few areas of interest based on objects. The default recommendation is to work only with a few objects with regards to understanding the complexities; therefore, the optimal division of “big data” meaningfully respects the following three levels:

- **Basic Level:** Default activities and analyses for data storage in data warehouse (internal matter).
- **Advanced Level:** Searching for links between stored data in a data warehouse and information sources in the global society (external matter).
- **Variable Level:** Searching for unexpected events based on complex statistics and mathematical methods with the support of Artificial Intelligence, Business Intelligence, Customer Intelligence, Competitive Intelligence, Swarm Intelligence (uncertainty matter).

Big data helps solve many difficulties in the global information society based on relations with database systems and intelligence implemented in various systems. There are well-known model cases for predicting and monitoring reserves, prices, or impacting the use of anything such as daily consumer goods, rare commodity, and also customer preferences and expected behavior and success based on specified metrics. This active implementation uses all the benefits of information technology with respect to IT user needs. The practical solution to existing difficulties is to connect information technology not only with well-known principles in this field, but also to respect people’s needs and people’s behavior. It is easy to add the important metrics “benefits and risks” into software evaluation. This metric

indicates the optimal solution in a specific case of IT implementation via all the above-defined levels. This is the multidimensional approach.

The above-mentioned levels are focused on internal, external and unexpected matters via a multidimensional approach. The adopted approach must have adequate reflection in the visualization of the needed data. Visualization is important as “a graphic manual” for quick and immediate work with data. In many cases, visualization has a close relation to simulation. The reason for this is that IT users modify the used data structure in simulation and receive immediate output in the form of various graphs. This basic rule respects almost all applications that work with big data and which provide graphic support for processed data. Big data and suitable analysis need an optimal data collection. Data quality is one of the frequent difficulties in many companies and organizations. Small businesses have similar difficulties. For easy data collection, it is better to divide data into three groups that follow the above defined levels of work with big data.

On the basic level, data are collected in a well-known structure based on verified rules from database systems and a warehouse. All IT users seemingly have information about the need to store data into information systems. There is an essential relational approach, working with objects and creating relations between the designed objects. The available information is focused on pragmatic data storage for customer registration, customer orders, storage records and invoicing. For this purpose, graphs are useful in the form of bar graphs, pie charts or line charts.

On an advanced level, IT users look at processed data from a higher perspective. This is not only a view based on the local conditions in a company or organization, but this view must be extended to global society. The reason is natural, we all live in a global information society. Information has an initial place where it is created and stored, but this information is not hidden and IT users share their own experiences, preferences

and difficulties with the provided services or products. In this situation, it is important to know the skills of the competitions, the opinion of the users on the realized activities, their preferences and requirements. This interest is focused on long time data monitoring via various places, interests, companies and customers. For these cases, good examples of graphical presentation are based on clusters or collections of various graphs (charts). These collections reveal more about outgoing changes, and IT users are interested in predicting future development.

Questions concerning future development bring our interest to the third level of work with big data. This level is characterized by unexpected conditions. These predictions are from one topic which is attractive for all IT users. Who would not want to know what is going to happen? Unfortunately, modern global society has a number of unbalanced conditions and phenomena. Companies and organizations are concerned about losing orders, are interested in the offered services, rapid changes in customer preferences, or development of new technologies. The solution to such difficulties is also a great challenge for big data. Interested IT users may see various clusters of graphs that are interconnected via various numbers of relations (lines). Analysts attempt to increase the transparency of the use of colors, the change of scale, or use statistical methods. The practical benefit is not clear, but this variable level is an inseparable part of the work with big data. The default links are on social media, and many companies and organizations use Facebook, Twitter and LinkedIn as supplementary information source for realized analyses. The problem is how to integrate high variable data into default data structures in static databases and warehouses. Based on these sites, streams of data are created in big volumes.

The difficulties for a number of designers and analysts are caused by indecision as to which work needs to be implemented. A unique solution and method do not exist and implementation of the verified methodology can bring false results.

Rapid developments and new approaches and technologies also bring a new vision for active IT product implementation. It is therefore suitable to use open access for available solutions, to add needed dimensions and phases based on actual reality such as individual pages into a note pad. A book is created which describes IT product implementation. Please see Table 1.

The pages of this book create the needed background for active work with big data. Realized simulations and visualizations may demonstrate an increased respect for current conditions, preferences and available skills, but every IT user asks about the default benefits for everyday activities. Measurable performance is at the centre of interest. For information technology, this performance is evaluated via specified metrics. There are no unique solutions and various metrics may be defined as time required for development, the number of distributions that were sold, representation on the market, the number of customers, the amount of income, the amount of costs. These metrics are evaluated with numbers (hard metrics), but there are metrics without an evaluation with any number (soft metrics). Good examples of soft metrics are the reputation of the company or organization, customer confidence, or also employee motivation. The question is how to divide the responsibility of individual dimensions and phases into measured benefits or weakness via defined metrics. A suitable solution is achievable through a scale that is assigned by individual preferences in an implementation team. Simulation with visualization once again provides an opportunity to display various solutions in relation to a defined scale, although only one is actually correct. Based on inspiration in nature, there are pheromones. For big data, these pheromones will indicate the best combination for dimensions and phases for suitable IT product development.

The practical use of this approach is simple. The designers and analysts select from the available dimensions and phases which are evaluated by their impact on the current reality and known

Table 1. Specification of individual dimensions and phases for IT product development in the dynamic changes of a global information society

Dimensions (With Defined Attributes and Methods)	IT Product Development		Phases
Function and Processes	Actual impact (pheromone) on reality for selected dimensions	Actual impact (pheromone) on selected phases	Communication
Data and Information			Disposition
Documentation			Evaluation
Hardware			Feasibility Study
Software			Coding
Management			Concept
Methodology and Methods			Construction iterations
Organizational issue			Implementation
Social Issue			Inception
Time and Level of Abstraction			Integration
Consultants and User Participation			Operations and Maintenance
Learning			Production
Data quality			Requirement gathering
End User Requirements			Retirement
Employee Approach			Software Design
Company Psychology			Sprint
Designed Concepts			Sprint Planning
Integration and Customization			System Analysis
Measurement and Evaluation			Testing
Simulations and Visualization			Transition

preferences. There is, for example, a project on upgrading software for communication support in a company. Based on the assigned impacts (pheromones), a book is created with the needed dimensions and phases for such an actualization. The suitable dimensions are:

- Consultant and user participation with learning.
- Data and information.
- Data quality.
- Documentation.
- Organizational issue.
- Time and level of abstraction.

And the suitable phases are:

- Coding.
- Communication.
- Evaluation.
- Integration.
- Requirement gathering.
- Sprint.
- Testing.
- Transition (release).

This approach combines various methodologies, methods and advice based on experience from IT product development. The benefit is flexibility with regards to the time and quality

request. The weakness of this approach can be ignorance of one of the important dimensions or phases for an active solution. In this situation, iteration helps add a needed dimension and phases. In other cases, additional dimensions and phases are selected based on current needs and recommendations. There is also the possibility of enabling more swarm intelligence based on current research (evolutionary algorithms as a dynamic complex system, differential evolution for ensemble strategies, decomposition and cooperative co-evolution technique, high exploration particle swarm optimization or a new efficient evolutionary multi-criterion optimization algorithm).

FUTURE RESEARCH DIRECTIONS

The multidimensional approach helps with sustainable development in all countries. The basic recommendation is to work with big data in context based on the multidimensional approach. The big data concept works with many terms and relations:

- Information technology.

(implementation in industry, realized analyses and statistics, transforming running processes, data balance, visualization, databases, applications and tools, simulations, and security)

- Actual conditions in firms, organizations, and individuals.

(to find the greatest benefit, to reduce existing risks, to respect cost reduction, to set optimal scales by preferences, to select suitable software)

- Urgent requests of the global society with preferences of individuals.

(to respond quickly to actual reality, to provide optimum quality, and other global challenges for technological regulation or unemployment)

The multidimensional approach gives rise to various partial views on big data such as:

- Information technology.
- Implemented software in firms, organizations and with individuals.
- Tools for better perception of context.
- Catalyst of people's reactions to ongoing changes.
- Protection against unwanted changes.

For IT development, the actual selection of needed dimensions and phases is based on the current impact (pheromone) for the given software product. This approach also has positive and negative aspects as with other methods and methodology. There is not unfortunately a unique solution for IT product development for all cases. The above-mentioned design of the method for IT product development provides higher flexibility and an opportunity to combine various views of a suitable solution. There is also space of course for mistakes and misunderstanding based on a lack of optimal skills and sources. Prevention of these weaknesses is an issue for further development and closer inspiration in swarm intelligence. It is suggestion for further research in this matter from global view.

CONCLUSION

A global information society brings both a number of benefits and weaknesses. The revolutionary possibilities are caused by information technology entering into everyday activities in various fields of human activities. Positive and negative experiences and requests are therefore well-known and collective experience and thinking have an important place in decision-making. In this reality, software development has major pressure from competitions, costumer requirements, contractors and also the development of new innovations and information technologies.

The suitable recommendation is to implement a multidimensional view on big data with all partial views like information technology, implemented software, tools for better perception of context, catalyst of people's reactions to ongoing changes, and protection against unwanted changes. The multidimensional view is a default part of a data warehouse, and this view also holds an optimal place in big data. Such an approach works with big data along three levels (internal matter as the basic level, external matter as an advanced level, and uncertainty matter as a variable level). These levels support benefits from information technology for the sustainable development of the global information society.

A considerable effort is needed for the definition of the order of this complexity. The basis for an active solution is a multidimensional approach, object access and inspiration from nature with regards to swarm intelligence. Based on pheromones, ants use this way for road marking, referring to the way or warning of danger. These kinds of activities are important for IT product development such as specification of the road for an adopted methodology, definition of a reference for needed dimensions and phases for IT development, and also as a warning against omissions and mistakes. The current impact is consequently defined as a pheromone for IT product development. The same impact is introduced for well-known dimensions and phases.

KEY TERMS AND DEFINITIONS

Big Data: The broad spectrum of data that have appeared throughout the development of the global information society.

Competition: A test of skill or ability of offered goods, services, and other realized activities in the global information society.

Global Society: A society where the creation and integration of data via information and knowledge is a significant process in all fields of human activities.

Information: Information is perceived data about the properties of existing objects. Information reduces uncertainty of the system.

Information Technology: Information technology is a scientific discipline that seeks the optimal solution for compiling, creating, linking and improving available technologies.

Sustainable Development: Economic development of the global information society that is conducted with respect to natural resources and global challenges like technological regulation, intellectual property protection, and unemployment.

Swarm Intelligence: Focus is dedicated to intelligent behavior swarms, i.e. large numbers of individuals. Nature is an inspiration for the designed method in many fields such as chemistry, engineering, environmental modeling, financial services and information technology.

Financing Micro, Small, and Medium Enterprises in Indian Industry

Shromona Ganguly

Indian Institute of Management Calcutta, India & Reserve Bank of India, India

INTRODUCTION

During the last five decades, the micro, small and medium enterprises (MSME) in the Indian economy has emerged as a dynamic and vibrant segment having a significant contribution towards employment generation and entrepreneurship formation. In addition, these enterprises play a crucial role in making the growth of the economy more inclusive by reducing regional disparity. During 2012-17, the MSME sector in India accounted for almost 38 per cent of GDP. The sector has grown approximately at a rate of 28.02 per cent and 26.42 per cent in terms of estimated number of enterprises and employment respectively during the period 2001-02 to 2006-07. Within the MSME sector, services constitute 80 per cent and manufacturing constitutes the remaining 20 per cent (Annual Report, Ministry of MSME, 2014-15).

Despite being an important contributor towards the national output and employment of the economy, the issue of timely and adequate availability of credit has been recognised as one of the major impediments to the growth of the sector in recent times. Recognising the problem of credit constraint faced by MSMEs, a slew of initiatives has been undertaken to make the financial system architecture of the sector more conducive for growth. However, the issue of credit availability to small firms became more important after the recent financial crisis which caused further slowdown in credit flow from formal banking system to the small firms.

Across the world, countries have followed different strategies to solve the issue of information

asymmetry and credit rationing in the small value loan market. However, adoption of these strategies primarily depends on the financial and legal system of the country. Typically, countries with advanced capital markets and strong legal and enforcement system use credit scoring, factoring, and leasing as alternative techniques to solve the issue of information asymmetry in small business loan segment (Berger and Udell 2006). However, due to weak enforcement, these strategies have limited effectiveness in developing countries. As a result, small firms in developing countries face larger credit constraints compared with countries which have well-developed financial systems. The existing literature on small firm financing discusses the issues and challenges from a cross-country perspective. There is a lack of detailed research on implications of country specific factors and financial system on small firm financing. The present essay aims to fill this gap by analysing the extent and nature of credit constraint faced by small firms in India.

The existing literature on small firm financing often analyses issues using the cross-country data. There are very few studies to understand the problems or complexities associated with small firm financing in the context of India. Further, deployment of technology assumes a key role in solving some of the structural issues embedded in the financial system of developing countries hindering credit flow to small businesses. At the same time, use of technology in the lending of small businesses raises important issues related to regulatory and policy responses to the online credit markets. So far, there is no comprehensive

study of these issues in the literature. The present chapter aims to fill this gap. The objective of the present chapter is to analyse the financial system of India in the context of lending to small firms and to what extent use of technology can solve the problem of lack of access to credit to small firms in India.

The chapter is organised as follows: The next section (Section 2) provides a brief of theoretical foundation and literature review on the financing of small firms around the world. Section 2 is further divided into two sub-sections focusing on the existing lending technologies in the context of small firm financing around the world and the how infusion of technology in financial market may change the landscape. Section 3 delineates the present status of credit flow to the MSME sector from the formal banking system. The section also discusses the issues and challenges involved in providing finance to the small businesses through the banking system in India. Section 4 describes in detail the present state of technology in the small business credit market in India. Section 5 concludes the study with observations and policy implications.

BACKGROUND AND LITERATURE REVIEW

Worldwide, access to finance has been a major challenge for small enterprises (Beck and Demircuc-Kunt 2006). The information asymmetry in the small business lending market can take the form of i) ex-ante screening of projects (adverse selection) or ii) ex-post monitoring of loan contracts (moral hazard). In the presence of information asymmetry, there exists an interest rate which maximizes expected return to the bank and beyond which, increasing the interest rate as a response to meeting credit demand could attract more risky borrowers resulting in a lower profit for the bank. As a result, banks prefer to ration credit in such a situation.

Lending Technologies in the Context of Small Firm Financing: Relationship-Based vs. Arm's-Length Systems

Worldwide, the financial systems can be classified into two broad categories; i) bank-based system as observed in the case of Germany and Japan ii) capital market based system as the one in UK and US. Typically financial institutions in an arm's length system rely on hard information in the form of financial system statements for loan disbursement as well as loan pricing. On the other hand, in a relationship-based system, the length of the relationship between a financial institution and borrower determines key terms of loan contract (Peterson and Rajan 1995).

Suggesting that the causality runs from finance to growth, Rajan and Zingles (2001) establishes the theoretical underpinning of the interdependence between the financial system and industrial structure. According to the study, the relative growth of industries is largely influenced by financial system structure of the country. Industries which require a higher amount of external financing will thrive in countries with developed financial systems. Similarly, countries with advanced financial system cater to the needs of young and innovative firms well which at a later stage, fuels the wave of creative destruction as alluded by Schumpeter (1911). Also, the study highlights the role of collateral in mitigating information asymmetry problems in developing countries. Accordingly, as the capital market of a country develops, equity financed industries tend to grow faster and use less fixed capital. This theory also establishes the link between equity market development and innovation. As innovation is typically an intangible asset, the growth of innovation-led industries requires the development of equity market to efficiently process soft assets like innovation. According to Wurgler (2000), countries with well-developed financial systems will invest more in growing industries while countries with the underdeveloped financial system will focus on declining industries.

The empirical literature on financial institution size and small firm financing often concludes that large financial institutions use sophisticated lending technologies and more often deals with the small business segment at an arm's length. In contrast, small and niche banks use relationship-based lending for catering the small size loan segment. As a result, these institutions are more efficient in dealing with the issue of information asymmetry prevalent in small business financing (Berger and Udell 2006).

Government-owned financial institutions are typically large and thus, following the argument presented above, these institutions are not best suited to cater the financial needs of small businesses. However, in many countries, large development banks owned by the government are entrusted with the mandate of credit disbursement to small firms. Often these are subsidised loans in the form of directed lending to specific sectors. In literature, there are mixed evidence on the efficacy of development banking model in credit disbursement to small businesses. Often, these institutions lack market discipline and cater the segment of small firms which are not creditworthy. In most cases, empirical evidence suggests that state ownership of banks is associated with more creditworthy firms getting excluded from the formal banking system (Beck and Levine 2004, Berger *et al* 2004). To further illustrate the functioning of development banks, Carvalho (2014) establishes that in Brazil, firms eligible for government subsidised loans expand employment in politically favoured regions. Further, these persistent expansions take place just before competitive elections, and are associated with lower future employment growth by firms in other regions. However, in many developing countries, state-owned development banks have played a crucial role in disbursing credit to industry at cheap cost and timely manner during the early stages of industrialization (Nayyar 2015).

However, Torre *et al* (2010) challenges this conventional wisdom about the relative efficiency of small and niche banks in small firm lending.

According to them, most banks in emerging economies look at the segment of small business as strategically important and deploy multiple techniques to extend loans to small business. Using the survey data of a balanced mix of developed and developing economies, the paper shows that the intensification of bank involvement with SMEs in various emerging markets is neither led by small or niche banks nor is it highly dependent on relationship lending. Moreover, large banks have relative efficiency in offering a wide range of products and services to micro and small businesses, due to increased use of technology and scale economies that these banks enjoy.

The Financial Crisis, “Perfect Storm,” and the Role of Technology in the Small Business Credit Market

The existing scholarly work on small firm financing underscores the adverse impact of the financial as well as debt crisis on the availability of credit to small firms (Jimenez and Ongena 2012, Iyer *et al* 2014, Udell *et al* 2016). In most of the studies, it was found that small firms are hit directly by reduction of loan supply by the financial institutions due to the following reasons (Mills and McCarthy 2014).

Increased Risk Perception

During the financial crisis, small businesses were hit the most in their sale and profit. In the US, a major portion of the small firms started facing increased problem of accessing bank credit as they became less credit worthy with reduced income and sales growth and increased cyclicity of their business operations.

Collateral

In the US, the sources of collateral were squeezed during the financial crisis, which in turn reduced the supply of credit to small businesses.

Rise-Averseness and Regulatory Overhang

During the financial crisis, banking regulators in the US responded by stipulating higher capital requirements for the banks. This, in turn, has reduced the availability of credit to small firms since the banks perceive these firms as high-risk and less creditworthy. Also, the impact of such regulatory overhang has partially neutralised the otherwise positive impact of the low interest rate and unconventional monetary policy pursued by major economies after the crisis.

However, one notable trend observed during the period of crisis as well as recovery is the emergence of a broad range of alternative lending technologies in the small business credit market. Typically, the new technologies have been evolving around receivable purchases and innovations in specialised lending by verticals. In addition, the online lending technologies have sprung up in major economies around the world. The google searches of “term loan” clearly indicate an upward trend during the last few years (Mills and McCarthy 2014). In most cases, the online players are acting as catalyst in infusing new technology in banking industry.

CREDIT FLOW TO SMALL BUSINESS IN INDIA

The Role of Commercial Banks

India’s financial system is known as bank-based. The banking system in India is predominated by public sector banks accounting for more than 70 per cent of total assets of the banking system. These banks played a critical role in mobilising financial savings and fuelling the industrial growth of the country during the early phases of industrialization in India. However, in India, the period before liberalization was characterised by significant command and control by the government in various sectors. In the case of the banking

sector, this took the form of high pre-emptions in the form of high reserve requirements. The policy of high reserve requirements often resulted in misallocation and mispricing of resources. Due to the adverse effects of excessive control of the financial sector in India, the pre-liberalization phase is often termed as the era of “financial repression” (Mohan 2004).

Though steps were taken from the mid-80’s to liberalise the credit delivery mechanism, this gained momentum only during the 90’s. As a part of the overall mandate of liberalization, the statutory liquidity ratio (SLR) was brought down from 38.5 per cent in 1992 to 25 per cent in 1997. Also, selective credit control was phased out in a gradual manner. To impose fiscal discipline as well as provide greater autonomy to monetary policy, automatic monetization of budget deficit was also prohibited.

The bank credit to GDP ratio increased in a slow but steady manner since the initiation of reform. The same trend is observable in the case of the sectoral credit to GDP ratio for the industry (manufacturing). However, it is noteworthy that despite various policy initiatives taken during the early 90’s, the growth in credit to GDP ratio became more pronounced only after 2000-01 (Figure 1). Despite a reduction in the statutory requirement ratio, banks in India continued investing in government securities as these assets were considered a safer haven for investment as compared to extension of credit to other sectors of the economy.

During the last two decades, industry accounts for almost 40 per cent of total bank credit in India. An interesting observation in this regard is that, since 1999, the credit flow from commercial banks to the industry has become a more long term in nature. Most of the long term borrowing is collateralized in nature. Hence, this trend, in some sense, indicates that within the total credit flow to industry, unsecured small account borrowings, typically by the smaller firms, have reduced over the years (Table 1).

Figure 1. Credit to GDP

Table 1. Type of account-wise outstanding credit of SCBs to industry (Rs million)

Year	Cash Credit	Overdraft	Demand Loans	Medium-Term Loans	Long-Term Loans	Total Credit to Industry	Total Bank Credit	Credit to Industry as Percentage of Total Credit	Share of Long-Term Loans in Total Credit to Industry

Source: Basic Statistical Return (BSR) of scheduled commercial banks in India, various issues

*: End-June. For all other years, data pertains to end-March

The aforementioned phenomenon becomes more visible from the size-wise composition of total industrial credit from the commercial banks. During the 80's as well as 90's, micro and small

enterprises accounted for, on an average, 25 per cent of total credit to the industry from the banks. This proportion has reduced to 15 per cent substantially after 2004-05. At the same time, large and

medium industries account for almost 85 per cent of total bank credit to industry during 2014-15, much higher than the proportion observed during 2003-04 (78 per cent) (Table 2).

Not only the absolute amount of bank credit flow to the small industries has come down during recent times, but the small industries located in rural areas also witnessed the sharpest fall in bank credit during recent times. Analysing the below table (Table 3), we get the following trends:

1. Out of the total bank credit outstanding in small borrowal accounts, the share of industry has declined from 16 per cent in 1996 to 4.2 per cent in 2006 and further, to 1.6 per cent in 2015.

2. While this decline of share in the industry in small borrowal account is uniform across geographical locations, the same is highest in the case of rural small borrowal accounts.
3. Within the small borrowal accounts (industry), the share of rural accounts has declined over the years (43 per cent in 1996 to 32 per cent in 2015).

In India, the public sector banks account for the largest commercial bank branch network of the country. These banks have a crucial role to play in making the banking system of India more inclusive. Apart from being the lynchpin of directed credit flow, public sector banks also play a pivotal role in furthering financial inclusion in hitherto underdeveloped part of the country. As per

Table 2. Size-wise classification of bank credit to industry (Rs crore)

Year	Micro and SMALL	Medium and Large	Industry	Total Bank Credit	Share of Industry in Total Bank Credit	Share of Micro and Small in Total Bank Credit to Industry	Share of Large and Medium in total Bank Credit to Industry

the bank-group wise data on credit flow to micro and small enterprises (MSE) sector, more than 75 per cent of total credit to MSE comes from the public sector banks, followed by domestic private banks (21 per cent) and foreign banks (4 per cent).

Issues and Challenges of Providing Credit to Small Enterprises Through the Commercial Banking Sector

The above section establishes the fact that there is a growing retrogression within the total credit flow to micro and small enterprises sector in India (Bhattacharya, 2013). Allen et al (2012), analysing the evolving financing channels of firms in India, concluded that alternative financing channel (non-bank, non-financial sources) is

quite significant for Indian firms in general, and small firms in particular. The finding is in sync with our finding in the previous section, which shows that total bank credit to the industry has grown in favour of large firms over the years. As pointed out by Bhattacharya (2013), this is in sharp contrast to what was expected after deregulation of interest rate in the Indian banking sector. Trends in bank credit to small businesses do not indicate any favourable impact resulting from interest rate deregulation, rather it indicates a higher amount of credit rationing in the small value loan segment in India. The preponderance of informal sources in the financing of small, unregistered manufacturing firms in India has been a reason for slower industrial growth of the country (Table 4).

Table 4. Financing pattern of unorganised manufacturing in India

Lending Institutions	2010-11			2005-06			2010-11		
	OAE	MHE	NHE	OAE	MHE	NHE	OAE	MHE	NHE

Source: Sen and Raj (2015)

As per the priority sector lending target mandated to commercial banks in India, banks are required to lend 40 per cent of their total lending towards specified sectors like agriculture and allied activities and micro and small enterprises. However, a number of public sector banks failed to meet the priority sector lending target as on March 2013. In addition, within the total lending to priority sectors, a trend of credit concentration is discernable towards the large accounts (RBI 2012).

The growing proportion of bank credit to industry in favour of large firms needs to be contrasted with the capital market development in India. Small businesses often lack the required financial track record to tap funds from the capital market. Hence these firms are more dependent on bank credit. As against this, our analysis shows that despite robust overall credit growth, credit to the MSE sector has come down substantially during the last decade. As a result, a growing proportion of small firms is moving to the informal markets as well as inter-firm credit market for financing their operation. As shown below, inter-corporate loan market has grown across all size categories of firms in recent times. During 1990-2010, inter-corporate loan as a proportion of total borrowing is most significant in the case of small firms (Figure 2).

Another seemingly puzzling fact is that despite the high-risk perception of the sector, MSE

sector's contribution remained stable in the non-performing assets (NPAs) of the commercial banks¹. As against this, large firms account for a growing proportion of total NPAs of banks in India. This trend suggests that banks are reluctant to extend credit to this sector due to ex-ante risk perception of the sector. Lack of formal financial intermediation of the sector is structural in nature and requires a re-look at the risk management and project appraisal practices followed in the Indian banking sector. At this juncture, an important policy question remains whether India needs the establishment of a special development bank catering issues related to industrial finance.

ISSUES AND CHALLENGES WITH SMALL FIRM FINANCING IN INDIA AND HOW TECHNOLOGY MAY CHANGE THE GAME

A significant proportion of entrepreneurs is self-financed in India (National Knowledge Commission 2008). Within the self-financed start-ups, a closer examination revealed that nearly two third of entrepreneurs have either invested their own savings or borrowed from an already existing family business. Banks constitute the next important source of finance for entrepreneurs in India and contribute almost 22 per cent of early stage

Figure 2. Inter-corporate borrowing in Indian manufacturing

Figure 3. Source of finance for start-up in India

financing of such enterprises. The role of venture capital and angel investors is rather limited in this respect; these together contribute 9 per cent of early stage financing in India (Figure 3).

The problem of financing the small firms has been catching the attention of policymakers in India for long. The need for creating the appropriate set of institutions for financing of small firms in India has been articulated by the committee of financial sector reforms (2008). However, it was also felt that along with creation of new financial institutions, the use of technology may change the financial landscape of small businesses in India. Since the micro and small business in India is largely affected by delayed payments by their corporate buyers, the Reserve Bank of India (RBI) has been contemplating the set up of an electronic trade receivable platform in India, largely in line with the NAFIN model of Mexican Development Bank (RBI, 2014). It is expected that with the infusion of technology, the credit flow to the micro businesses in India without any credit history will improve in the near future.

CONCLUSION

The chapter analyses in detail the role played by formal and informal financial institutions in India

in providing credit to the micro and small firms in Indian industry. The discussions presented in the previous sections suggest three key trends discernible in this respect:

- There is a growing pattern of credit retrogression observable in the case of bank credit flow to industry. Over the years, large firms account for an increasing amount of total credit flow to the industry while the share of small firms has come down.
- The informal financial sector still accounts for a significant amount of total financing of the sector. This trend has not changed much despite various initiatives were undertaken by the Reserve Bank to expand the outreach of the banking system.
- Self-financing predominates the early stage financing pattern for start-ups in India. Banks, though constitute the second largest source of early stage debt finance, have limited outreach for rural entrepreneurs. The alternative financing channels, which include venture capital and private equity funds, constitute less than 10 per cent of total early stage financing in India. This figure is much lower compared with the advanced economies.

FUTURE RESEARCH DIRECTIONS

In recent times, the policy environment for the micro and small enterprises sector in Indian industry has kept its thrust on increasing the credit flow from the formal banking system to the MSEs. This includes the introduction of new innovative techniques like credit scoring, and use of technology to deepen the market for factoring in India. Apart from use of such new techniques, a new bank with active government involvement (Mudra Bank) has been created to monitor and provide credit to rural entrepreneurs. However, use of new lending technology to the small business in India also requires an overhaul of the regulatory approaches towards the new technologies introduced in the credit market. For example, during the last few years the peer to peer lending market has been taking its root in India. The discussion paper released by the Reserve Bank (RBI, 2016) articulates the need for the overall monitoring of the sector from the perspective of financial sector stability, while recognising the benefit it provides to various stakeholders. In this regard, the policy challenge is to achieve the optimal amount of oversight for the new technologies evolving in the small business credit market which will prevent abuse or fraud without preventing innovation.

KEY TERMS AND DEFINITIONS

Adverse Selection: The concept of adverse selection applies to a case where the bad customers apply for the service because they have better information about how much benefit can be extracted from the service.

Development Banks: Specialised banks created for subsidised directed lending to specific sectors.

Information Asymmetry: Information asymmetry deals with the decision of transaction in situations where one party has more information compared to the other.

Unconventional Monetary Policy: Unconventional monetary policies are used in a situation where the interest rate has reached near zero. These include quantitative easing, forward guidance and signalling.

Software Development Process Standards for Very Small Companies

S

Rory V. O'Connor
Dublin City University, Ireland

INTRODUCTION

In recent times quality orientated process approaches and standards have matured and gained acceptance in many software development organizations. Standards emphasize communication and shared understanding more than anything. There are many potential benefits of using standards. In particular for small and very small companies, the benefits that certification can provide include: increased competitiveness, greater customer confidence and satisfaction, greater software product quality, increased sponsorship for process improvement, decreased development risk, facilitation of marketing, and higher potential to export. While good internal software management might help meet the first five claims; the last two can only be the benefits of using a widely recognized standard.

It is commonly agreed that very small software companies, implementing management procedures, and controls to appropriately administer their software development activity is a significant challenge (Laporte et al, 2015). For example, a software company operating in India may have a completely different set of operational problems when compared to a software company in Canada, Mexico or Ireland. Even within a single geographical area such as Ireland, the range of operational issues faced by a small local Irish-owned firm can be radically different to those affecting a multinational subsidiary. The fact that all companies are not the same raises important questions for those who develop software process

and process improvement models. To be widely adopted by the software industry, any process or process improvement model should be capable of handling the differences in the operational contexts of the companies making up that industry. But process improvement models, though highly publicized and marketed, are far from being extensively deployed and their influence in the software industry therefore remains more at a theoretical than practical level.

With this in mind, the standardization body ISO/IEC has recently published the ISO/IEC 29110 standard “Lifecycle profiles for Very Small Entities” with the overall objective being to assist and encourage very small software organization in assessing and improving their software. The purpose of this chapter is provide a primer on the ISO/IEC 29110 standard focusing on two main process areas of Project Management and Software Implementation. This chapter will start with an explanation of the rationale and justification for the development of this new standard, followed by an overview of its structure and explain how to deploy ISO/IEC 29110 in a typical very small software company.

BACKGROUND

This section will introduce the problem with standards and explain the specific case of very small entities, before presenting the ISO/IEC standard as a solution specifically designed to address these problems for very small companies.

Very Small Companies

The definition of “Small” and “Very Small” Entities is challengingly ambiguous, as there is no commonly accepted definition of the terms. The term “Very Small Entity” (VSE) had been defined by the ISO/IEC JTC1/SC7 Working Group 24 and subsequently adopted for use in the new ISO/IEC 29110 software process lifecycle standard as being “an entity (enterprise, organization, department or project) having up to 25 people” (Laporte et al, 2008).

A large majority of enterprises worldwide are VSEs. In Europe, for instance, as illustrated in Table 1, over 92% of enterprises are micro-enterprises. They have fewer than nine employees. Micro enterprises account for 70% to 90% of enterprises in OECD countries and about 57% in USA.

Typically VSEs are economically vulnerable as they are driven by cash flow and depend on project profits, so they need to perform the projects within budget. They tend to have low budgets which have many impacts, such as: lack of funds to perform corrective post delivery maintenance; few resources allocated for training; little or no budget to perform quality assurance activities; no budget for software reuse processes; low budget to respond to risks; and limited budget to perform Process Improvement and / or obtain a certification/assessment. Typically the VSE’s product has a single customer, where the customer is in charge of the management of the system and the software integration, installation and operation. It is normal practice for the customer not to

define quantitative quality requirements and for customer satisfaction to depend on the fulfillment of specific requirements that may change during the project. A close relationship between all involved project members including the customer shows that software development in small and very small companies is strongly human-oriented and communication between them is important.

The internal business process of VSEs is usually focused on developing custom software systems, where the software product is elaborated progressively and which typically does not have strong relationship with other projects. Typically most management processes (such as human resource and infrastructure management) are performed through informal mechanisms, with the majority of communication, decision-making and problem resolution being performed face-to-face.

Problems With Standards

Although commercial SPI models have been highly publicized, they are not being widely adopted and their influence in the software industry therefore remains more at a theoretical than practical level (O’Connor and Coleman, 2009). For example, in the case of Capability Maturity Model Integration (CMMI), an Australian study found that small organizations considered that adopting CMMI would be infeasible (Staples et al, 2007) and an Irish study found significant resistance due to negative perceptions surrounding levels of bureaucracy and required documentation (Coleman and O’Connor, 2006). Further investigation of the CMMI by Staples and Niazi (2006) discovered, after systematically reviewing 600 papers, that there has been little published evidence about those organizations who have decided not to adopt CMMI.

There is evidence that the majority of small and very small software organizations are not adopting existing standards / proven best practice models because they perceive the standards as being developed by large organizations and orientated towards large organizations, thus provoking the

Table 1. Size of enterprises in Europe (Moll, 2013)

Type	Number of Employees	Annual Turnover	No. of Enterprises (% of Overall)
Micro	1-9	≤2M	92.2
Small	10-49	≤10M	6.5
Medium	50-249	≤50M	1.1

debate the in terms of number of employees, size does actually matter (O'Connor and Coleman, 2008a). Studies have shown that small firms' negative perceptions of process model standards are primarily driven by negative views of cost, documentation and bureaucracy. In addition, it has been reported that SMEs find it difficult to relate standards to their business needs and to justify the application of the international standards in their operations. Most SMEs cannot afford the resources for, or see a net benefit in, establishing software processes as defined by current standards and maturity models (O'Connor and Coleman, 2008b).

ISO/IEC 29110 Standard Proposed

Accordingly there is a need to help such organizations understand and use the concepts, processes and practices proposed in the ISO/IEC JTC1/SC7's international software engineering standards. The ISO/IEC 29110 standard "Lifecycle profiles for Very Small Entities" is aimed at addressing the issues identified above and addresses the specific needs of VSEs. The approach (Laporte et al, 2013a) used to develop ISO/IEC 29110 (2001) started with the pre-existing international standard ISO/IEC 12207 (2008) dedicated to software process lifecycles. The overall approach consisted of three steps: (1) Selecting ISO/IEC 12207 process subset applicable to VSEs of up to 25 employees; (2) Tailor the subset to fit VSE needs; and (3) Develop guidelines for VSEs.

Furthermore, in late 2009, the International Council on Systems Engineering (INCOSE) Very Small and Micro Entities Working Group (VSME) was established to evaluate the possibility of developing a standard, using the Generic profile group scheme of the ISO/IEC 29110 series, based on ISO/IEC 15288 (2008), for organizations developing systems. Late 2011 saw the launch of the official development of the systems engineering ISs and TRs for VSEs. In August 2014, ISO published the ISO/IEC 29110 systems engineering and management guide of the Basic profile ISO/IEC TR 29110-5-6-2:2014 (2014). The systems

engineering and management guide of the Entry profile has been published in 2015 as ISO/IEC TR 29110-5-6-1:2015 (2015). Similar to the existing set of software ISO/IEC 29110 TRs, the Management and Engineering Guide for systems engineering should also be made available at no cost by ISO (Laporte et al, 2014).

STRUCTURE OF ISO/IEC 29110

The basic requirements of a software development process are that it should fit the needs of the project and aid project success. And this need should be informed by the situational context where in the project must operate and therefore, the most suitable software development process is contingent on the context. The core situational characteristic (Clarke and O'Connor, 2012) of the entities targeted by ISO/IEC 29110 is size, however there are other aspects and characteristics of VSEs that may affect profile preparation or selection. Creating one profile for each possible combination of values of the various dimensions introduced above would result in an unmanageable set of profiles. Accordingly VSE's profiles are grouped in such a way as to be applicable to more than one category. Table 2 illustrates a Profile Group, which contains three profiles (labeled A, B and C) that are mapped to nine combinations of business models and situational factors.

Profile Groups are a collection of profiles, which are related either by composition of processes (i.e. activities, tasks), or by capability level, or both. The "Generic" profile group is applicable

Table 2. Allocating VSE characteristics to profile groups

Business Models	Profile Situational Factors		
	Critical	User Uncertainty	Environment Change
Contract	Profile A	Profile A	Profile A
In-House	Profile C	Profile B	Profile A
Commercial	Profile B	Profile A	Profile A

to a vast majority of VSEs that do not develop critical software and have typical situational factors. This profile group does not imply any specific application domain, however, it is envisaged that in the future new domain-specific sub-profiles may be developed in the future. Table 3 illustrates this profile group as a collection of four profiles, providing a progressive approach to satisfying the requirements of profile group. To date the Basic Profile has been published, the purpose of which is to define a software development and project management guide for performing one project at a time.

Engineering and Management Guide

At the core of this standard is a Management and Engineering Guide, officially known as ISO/IEC TR 29110-5-1-2 (2011), which focuses on *Project Management* and *Software Implementation* as illustrated in Figure 1. The purpose of the Basic Profile is to define Software Implementation (SI) and Project Management (PM) processes from a subset of ISO/IEC 12207 (2008) and ISO/IEC 15289 (2011) appropriate for VSEs, as illustrated in Figure 1.

Project Management Process

The purpose of the Project Management (PM) process is to establish and carry out the tasks of the

Table 3. Graduated profile of the Generic profile group.

Generic Profile Group			
Entry	Basic	Intermediate	Advanced

software implementation project in a systematic way, which allows compliance with the project's objectives in terms of expected quality, time, and costs (O'Connor and Laporte, 2012). The seven objectives of the PM process are listed in table 4.

Figure 2 illustrates the 4 activities of the project management process as well as their input and output product. The four activities of the Project Management Process are:

- **Project Planning:** The primary objective of this process is to produce and communicate effective and workable project plans. This process determines the scope of the project management and technical activities, identifies process outputs, project tasks and deliverables, establishes schedules for project task conduct, including achievement criteria, and required resources to accomplish project tasks.

Figure 1. ISO/IEC 29110 project management and software implementation relationship

Table 4. Objectives of the project management process of the basic profile (ISO/IEC TR 29110-5-1-2, 2011)

Objective	Description
PM.O1	The Project Plan for the execution of the project is developed according to the Statement of Work and reviewed and accepted by the Customer. The tasks and resources necessary to complete the work are sized and estimated.
PM.O2	Progress of the project is monitored against the Project Plan and recorded in the Progress Status Record.
PM.O3	The Change Requests are addressed through their reception and analysis. Changes to software requirements are evaluated for cost, schedule and technical impact.
PM.O4	Review meetings with the Work Team and the Customer are held. Agreements are registered and tracked.
PM.O5	Risks are identified as they develop and during the conduct of the project.
PM.O6	A software Version Control Strategy is developed. Items of Software Configuration are identified, defined and baselined. Modifications and releases of the items are controlled and made available to the Customer and Work Team including the storage, handling and delivery of the items.
PM.O7	Software Quality Assurance is performed to provide assurance that work products and processes comply with the Project Plan and Requirements Specification.

- **Project Plan Execution:** To implement the actual work tasks of the project in accordance with the project plan. Ideally when the project plan has been agreed and communicated to all teams members, work of the development of the product, which is the subject of the project, should commence.
- **Project Assessment and Control:** Purpose is to determine the status of the project and ensure that the project performs according to plans and schedules, within projected budgets and it satisfies technical objectives.
- **Project Closure:** Typically involves releasing the final deliverables to the customer, handing over project documentation to the business, terminating supplier contracts, releasing project resources and communicating project closure to all stakeholders.

For illustration purposes, two tasks of the Project Planning activity are listed in Table 5. The project manager (PM) and the customer (CUS) are involved in these 2 tasks. The customer is involved, during the execution of the project, when he submits change requests, during project review meetings, for the validation and approval of the requirements specifications and for the acceptance of the deliverables.

Software Implementation Process

The purpose of the Software Implementation (SI) process, illustrated in Figure 3, is to achieve systematic performance of the analysis, design, construction, integration, and test activities for new or modified software products according to the specified requirements. The seven objectives of the SI process are listed in Table 6.

Table 5. Example of 2 tasks of the project planning activity (ISO/IEC TR 29110-5-1-2, 2011)

Role	Task	Input	Output
PM CUS	PM.1.2 Define with the Customer the Delivery Instructions of each one of the Deliverables specified in the Statement of Work.	Statement of Work [reviewed]	Project Plan Delivery Instructions
PM CUS	PM.1.14 Review and accept the Project Plan. Customer reviews and accepts the Project Plan, making sure that the Project Plan elements match with the Statement of Work.	Project Plan [verified]	Meeting Record Project Plan [accepted]

Figure 2. ISO/IEC 29110 project management process

Table 6. Objectives of the software implementation process of the basic profile

Objective	Description
SI.O21	Tasks of the activities are performed through the accomplishment of the current Project Plan.
SI.O2.	Software requirements are defined, analyzed for correctness and testability, approved by the Customer, baselined and communicated.
SI.O3.	Software architectural and detailed design is developed and baselined. It describes the Software Components and internal and external interfaces of them.
SI.O4.	Software Components defined by the design are produced. Unit test are defined and performed to verify the consistency with requirements and the design. T
SI.O5.	Software is produced performing integration of Software Components and verified using Test Cases and Test Procedures. Results are recorded at the Test Report.
SI.O6.	A Software Configuration, that meets the Requirements Specification as agreed to with the Customer, which includes user, operation and maintenance documentations, is integrated, baselined and stored at the Project Repository.
SI.O8.	Verification and Validation Tasks of all required work products are performed using the defined criteria to achieve consistency among output and input products in each activity.

The activities of the Software Implementation Process are:

- **Software Implementation Initiation:** Ensures that the Project Plan established in Project Planning activity is committed to by the Work Team.
- **Software Requirements Analysis:** Analyzes the agreed Customer's requirements and establishes the validated project requirements.

The activity provides:

- **Software Architectural and Detailed Design:** Transforms the software requirements to the system software architecture and software detailed design.
- **Software Construction:** Develops the software code and data from the Software Design.
- **Software Integration and Tests:** Ensures that the integrated Software Components satisfy the software requirements.
- **Product Delivery:** Provides the integrated software product to the Customer.

IMPLEMENTING THE ISO/IEC 29110 STANDARD

In order to facilitate the implementation, by VSEs, of a Profile, a set of Deployment Packages (2013) are available. A deployment package is a set of artifacts developed to facilitate the implementation of a set of practices, of the selected framework, in a VSE. A deployment package is not a process reference model (i.e. it is not prescriptive). The elements of a typical deployment package are: description of processes, activities, tasks, roles and products, template, checklist, example, reference and mapping to standards and models, and a list of tools. Deployment packages are not intended to preclude or discourage the use of additional guidelines that VSEs find useful.

The elements of a typical deployment package are: technical description, relationships with ISO/IEC 29110, key definitions, detailed description of processes, activities, tasks, roles and products, template, checklist, example, references and mapping to standards and models, and a list of tools. The mapping is only given as information to show that a Deployment Package has explicit links to Part 5, ISO standards, such as ISO/IEC 12207, or models such as the CMMI developed by the Software Engineering Institute. Hence by deploying and implementing a package (O'Connor and Sanders, 2013) a VSE can see its concrete step to achieve or demonstrate coverage to Part 5.

The working group (ISO/IEC JTC1/SC7 WG 24) behind the development of this standard is advocating the use of pilot projects as a mean to accelerate the adoption and utilization of ISO/IEC 29110. Pilot projects are an important means of reducing risks and learning more about the organizational and technical issues associated with the deployment of new software engineering practices. Pilot projects are based on the ISO/IEC 29110-5 Management and engineering guide and the deployment package(s).

To date a series of pilot projects have been completed in several countries utilizing some of the deployment packages developed. For example Ribaud et al. (2010) have documented the results of one pilot project that conducted with a 14-person VSE based in France, which successfully implemented ISO/IEC 29110 processes practices utilizing the available Deployment Packages. From which they have identified some potential additional infrastructure and support process activities and suggestions for future evolution of ISO/IEC 29110 Process Profiles. A further series of pilot projects are currently underway in research laboratories and enterprises in Canada, Ireland, Belgium and France, with further pilot projects planned in the near future.

The results from one pilot study in Canada concluded that the tools developed to support the project management processes proved very useful and helped the project managers rapidly

Figure 3. ISO/IEC 29110 software implementation process

integrate the knowledge required to execute the processes (Laporte et al, 2013b). In the case of this trial company, for the first time, the company has documented management processes for small-scale projects. Besides, some project managers have joined forces to promote project management practices within this engineering firm's division. The improvement programme was so successful

that managers of the company's other divisions have shown an interest in learning this approach in order to implement it within their respective divisions.

Laporte et al (2015) report on two successful trials of ISO/IEC 29110, that demonstrate it was possible to properly plan the project and develop the software product using proven software prac-

tices documented in standards as well as not interfering with the creativity during the development of their web site. People who think that standards are a burden, an unnecessary overhead and a treat to creativity should look at this start-up project and revisit their results.

CONCLUSION

For most enterprises, but in particular for VSEs, international certifications can enhance credibility, competitiveness and access to national and international markets. Brazil has led the development of an ISO/IEC 29110 certification process. An ISO/IEC 29110 auditor should be competent in auditing techniques, have expertise in ISO/IEC 29110 and have experience in software development. For VSEs, such a certification should not be too expensive and short. The certification process has been successfully piloted in a few VSEs.

Finally, research studies have been undertaken to understanding the perception of VSEs towards the adoption of process standards (Basri et al, 2010) and also to evaluate management sentiment towards ISO/IEC 29110 (O'Connor, 2012) and management commitment to SPI and ISO/IEC 2910 in particular in Europe (O'Connor et al, 2010) and South America (Sanchez-Gordon et al, 2015). These revealed that the acceptance level of any type or model of software quality or lifecycle standard in VSEs is a very low priority item, but the level of awareness of standards and potential benefits was high. Furthermore these studies showed the main reason for not adopting standards was a lack customer requirement, a lack of resources and the perceived difficulties in defining an organizational process. Furthermore, this analysis reveals a pattern that indicates that the acceptance level of quality standard such as ISO among VSEs are still low even though the staff and management are knowledgeable and aware the benefit of adopting such standards. The main reasons are more related to the lack of the customer requirement and the limited resources

in the company. In addition the perception a heavyweight process especially in terms of documentation, cost and non- alignment with current development process are among the reasons why the companies did not plan to adopt a lifecycle standard in the short to medium term. However from the analysis, VSEs may still be interested in lifecycle standards if certain important criteria are met and such standards are closely related to their needs. Therefore it can be concluded that the market and demand for ISO/IEC 29110 in VSEs has a positive outlook.

FUTURE RESEARCH DIRECTIONS

In terms of future work, as ISO/IEC 29110 is an emerging standard there is much work yet to be completed (O'Connor and Laporte, 2014). The main remaining work item is to finalize the development of the remaining three profiles: (a) Entry – a six person-months effort project or a start-up VSEs; (b) Intermediate - Management of more than one project and (c) Advanced - business management and portfolio management practices. In addition the development of additional Profile Groups for other domains such as critical software, game industry, scientific software developments are being studied.

Whilst work is currently underway on an assessment mechanism for ISO/IEC 29110, a clear niche market need is emerging which may force the process assessment community to change their views on how process assessments are carried out for VSEs. In particular there is a strong need to ensure that VSEs are not required to invest the anything similar in terms of time, money and other resources on process assessments, as may be expected from their larger SMEs (small and medium enterprises), or even MNC (multinational corporations) counterparts. Indeed some form of self-assessment, possibly supported by Internet based tools, along with periodic spot-checks may be suitable alternative to meet the unique needs of VSEs.

KEY TERMS AND DEFINITIONS

Process Assessment: The disciplined examination of the processes by an organisation against a set of criteria to determine capability of those processes to perform within quality, cost and schedule goals.

Project Implementation: Is defined as a specified set of activities designed to put into practice an activity or program of known dimensions.

Project Management: This is the process and activity of planning, organizing, motivating, and controlling resources to achieve specific goals.

Software Process: A set of activities, methods, practices and transformations that people use to develop and maintain software and the associated products.

Software Process Improvement (SPI): Aims to understand the software process as it is used within an organisation and thus drive the implementation of changes to that process to achieve specific goals such as increasing development speed, achieving higher product quality or reducing costs.

Very Small Entity: An enterprise, organization, department or project having up to 25 people.

Adolescents' Food Communication in Social Media

Christopher Holmberg

University of Gothenburg, Sweden

INTRODUCTION

Social media is ubiquitous in the lives of adolescents. The Swedish Media Council (2015) reports that 91% of Swedish adolescents between 13 and 16 years old use social media sites such as Facebook or Instagram and similar numbers exist in the US (Lenhart, Smith, Anderson, Duggan, & Perrin, 2015). Social media are usually defined as Internet-based services that permit users to construct personal profiles, generate and access searchable online content (e.g., images, videos), form online connections with other users, and view these social connections (CDC, 2011).

Considering the widespread use of social media, it is no surprise that much of the communication in these networks concern food and nutrition. Previous studies show that the dissemination and sharing of food content is prevalent in many of these channels (Holmberg, Chaplin, Hillman, & Berg, 2016). As Neely, Walton, and Stephens (2014) noted, the communication of food mirrors social and cultural values, and the social aspects of young people's food practices are important components of their wellbeing and health. Social media provides a unique opportunity to study adolescents' food communication without interfering with it, and in order to gain a better understanding of what food means to adolescents, it is crucial to study their online food communication.

Adolescents' online food communication is a pressing matter because online food communication affects adolescents in both positive and negative ways with regard to health (Holmberg, 2016). Not only does messages of food in social media platforms and channels serve a symbolic purpose

concerning socio-cultural aspects of communication and discourse. A meta-analysis by van Meer et al. (2015) shows that food communication, such as food images, affects brain areas associated with appetite. Other experimental studies show that food communication in social media can affect dietary behaviors among adolescents (Bevelander, Anschutz, Creemers, Kleinjan, & Engels, 2013).

The goal of this chapter is to introduce a promising research direction regarding adolescents' food-related communication in social media. The objective is to elucidate the complex and interwoven relationship between food and nutrition, social media, and adolescents from a health promotion perspective. As such, this article will draw upon empirical studies and results as well as conceptual and methodological research literature.

BACKGROUND

The social nature of food and food practices - that is, the idea that food is a way to interact and connect with others - is crucial to promoting health. To better understand food and its complex relationship with social media, we need to consider how diets and food habits connect people culturally. While food and nutrients are necessary for human survival, they also function as important objects in culture and as rich sources for metaphor (Korthals, 2008). Some sociologists even aver that food is a total social fact (Mauss, 1967). The cultural dimension of food practices has been termed the "omnivore's dilemma" (Korthals, 2008) or "omnivore's paradox" (Fischler, 1988), based on the assumption that humans can eat a wide variety

of things. Unlike specialized eaters, omnivores such as humans can thrive on a multitude of diets and lack inherent predilections for foods that are healthy. Culture thus becomes a primary factor that dictates human eating behaviors, which suggests that the social meaning and metaphors of food can affect food choices and implicate which types of food confer social acceptance.

Given that young people are heavy users of social media and that their usage is generally difficult for parents and guardians to monitor (McBride, 2011), it becomes critical to examine health and food messages in those channels. Research demonstrates that the adolescent period is marked by changes in body composition, physical activity, diet habits, and psychological issues. These issues put youths at an increased risk of adapting unhealthy lifestyles (Alberga, Sigal, Goldfield, Prud'homme, & Kenny, 2012). As Vuk Pisk et al. (2012) have documented, adolescence is therefore a critical time for identity formation and a very sensitive period where social ties and relationships with others grow in importance. Since adolescents' social networks function as important influences for their dietary habits, researchers in many fields, such as obesity research, emphasize the importance of further exploring these social network effects.

FOOD CONTENTS IN NUMEROUS SOCIAL MEDIA

Communication includes both the sending and receiving of messages. Online, adolescents are exposed to messages relating to food, but they also act as uploaders of food-related content such as images or videos of food items. Along these lines, there are a growing number of studies highlighting ways in which food communication is perpetuated through different types of social media applications.

Food blogs provide information and inspiration regarding recipes, meal ideas, and food items. As such, they have the capacity to shape

adolescents' social norms regarding how, what, and where to eat. Schneider et al. (2013) found that popular American food blogs met energy recommendations but were excessive in saturated fat and sodium. The authors therefore suggested that the public should be aware of the nutritional limitations of common food blogs. Simunaniemi et al. (2011) analyzed how laypeople blogged about fruits and vegetables. The study revealed that the bloggers approached fruit and vegetables through either lived or mediated experiences and that self-expression that aimed to influence others' diets was common in these blogs. There are also examples of how blogs are used to foster controversial dietary practices. Using the spreadable media theory (Jenkins, Ford, & Green, 2013), research has shown that blogs allow for non-conventional experts to circumvent traditional peer-review processes by publishing in the public domain. Holmberg (2015) uses the example of how prominent low-carb high fat diet promoters in Sweden could reach a wide audience and appeal to a like-minded community of dieters by using self-made blogs and websites. Also microblogs such as Twitter have been analyzed in regards to food communication. Hingle et al. (2013) found that Twitter can provide a method for observing real-time food consumption and that this type of data visualization may present a method of identifying relationships between diet and behavior.

Media-sharing sites popular with adolescents, such as YouTube also propagate large amounts of food and diet information. Cerri et al. (2012) showed that a large number of the videos on YouTube labeled with the word "diet" did not contain this information. The researchers also found that a majority of the videos did not contain scientifically sound information and that videos often contained incomplete information. Boyd and Ellison (2007) defined social network sites as:

... web-based services that allow individuals to (1) construct a public or semi-public profile within a bounded system, (2) articulate a list of other users

with whom they share a connection, and (3) view and traverse their list of connections and those made by others within the system. (p. 211)

Facebook is the world's largest online social network site and it is no surprise that food-and-nutrition related content has been studied on this platform. Lohse (2013) found that Facebook is an effective strategy to recruit participants to nutrition education programs. There are also less healthy occurrences taking place on Facebook. Freeman et al. (2014) found that food companies promoting high calorie low nutrient food items (e.g. Coca-Cola) utilize the interactive aspects of Facebook to market their products. The study showed that these companies capitalize on users' social networks to magnify the reach and personal relevance of their marketing. Young users were particularly prone to this kind of online food marketing. A social network especially popular with younger individuals is Instagram (Pew Research Center, 2015). Studies have investigated both the food-related content on Instagram (Hu, Manikonda, & Kambhampati, 2014) and the overall communication of food images from the perspective of adolescents (Holmberg et al., 2016). Holmberg et al. (2016) found that food images shared on Instagram by adolescents was dominated by foods characterized as high calorie and low nutrient such as sodas and candy.

Why Can It Be Problematic?

As noted in previous examples food marketing transmitted through social media outlets are frequently transmitted by food companies producing less health food items. Montgomery and Chester (2011) outlined five kinds of digital marketing techniques that are used by fast food companies to target adolescents: 1) augmented reality; such as online virtual environments that can decrease conscious attention to marketing techniques, 2) methods that include surveillance of users' behaviors online, 3) data gathering and behavioral tailoring intended to distribute individualized

marketing, 4) location targeting which follow adolescents' activities and are able to link point of influence to point of purchase, 5) neuro-marketing, which draws on neuroscience methods to design digital marketing techniques intended to activate subconscious and emotional arousal. Many of these intrusive practices are intentionally aimed to draw on unconscious processes, circumventing the rational decision making that is central to the system of just marketing.

These integrated food advertisement campaigns reinforce commercial messages across several online platforms to engage individually with users. These campaigns may have greater impact than that of conventional marketing, especially among adolescent consumers (Kelly, Vandevijvere, Freeman, & Jenkin, 2015). Food brands have been noted to be a key factor in the success of food marketing. The perceptions of brands changes as children become older; children learn how to recognize commercial, supermarket and budget brands and attach different meaning to these brands. Roper and La Niece (2009) found that food brands were important for British schoolchildren, and they also noted that peers become more influential to consumption decisions as children move through the tweens. In their study, peer approval substituted family as the major influence behind consumption behavior.

This behavior seems to be perpetuated in social networking sites. Holmberg et al. (2016) found that labeled food products were highly prevalent in food images uploaded by adolescents on Instagram. Like the British study (Roper & La Niece, 2009), the presentation and display of certain food brands were important to present to peers in the adolescents' social networks. The idea of food as a signifier of status is not novel. Bourdieu (1984) critically discussed that our preferences for certain foods are reflected by our social position, and are themselves acts of social positioning. What is new however, is the pace and means by which food is communicated today. Food is no longer seen just as essential for the body; it has become a currency that can be used online for social status.

Adolescents may increase their social capital by sharing desirable meals and food items through social media. In order to understand adolescents' practice of online food communication we need to delve further into the theoretical concepts surrounding adolescents' social food practices. Therefore, this chapter will continue to focus on online social networks which explore social dynamics among adolescents and how they could influence dietary habits and food consumption in different ways.

THEORETICAL FRAMEWORKS THAT CAN ADVISE RESEARCH

It is significant to recognize adolescents' influence on food choices and their active role in conveying family practices and customs. A review of youths' food practices and social relationships showed that food practices play multifaceted roles in adolescents' social lives, and that food communication influence different aspects of their social relationships. Aspects such as caring, sharing, integrating, trusting, interchanging, negotiating, and belonging was some of the features of relationships that were affected through adolescents' different food practices (Neely et al., 2014). Salvy et al. (2012) sorted the influence of peers on adolescents' eating habits into impression management, and social facilitation and modeling. They also refer to the normative framework, put forth by Herman et al. (2003), while attempting to assimilate research concerning these collective mechanisms.

Impression Management and Social Facilitation

boyd (2007) draws on the work of Goffman (1959) when defining impression management among adolescents in online interaction. According to boyd, adolescents seek to define social situations online by using signs from the context around them. Social norms arise out of situations as adolescents learn to interpret cues from the environment and

apprehend what considers appropriate behavior. The management of impressions is a vital social skill that is refined through experience. The adolescents learn how to create meaning out of a situation and others' reactions over time. boyd further argues that adolescents in a sense have more control online as they are able to more deliberately choose what information to put forward, thus reducing impulsive and spontaneous reactions that might have leaked out in everyday interaction. This understanding is important as the adolescents, to varying degrees, have an active choice in what kind of food communication they are transmitting online. Previous research indicates that in the presence of others, individuals tend to eat more than when eating alone. The leading explanation for the social facilitation of eating is the time-extension premise, which claims that the company of others ultimately encourages increased eating by prolonging the duration of the meal (Pliner, Bell, Hirsch, & Kinchla, 2006). However, overweight adolescents in experimental studies eat less snacks in social situations than normal weight adolescents, eat more when alone, and also eat more in the presence of overweight peers than in the presence of leaner peers (Salvy, 2009). For adolescents who are overweight or obese, other processes may overtake social facilitation. For instance, when considering the strong connection between overweight status and social stigma, it is credible to assume that overweight youths are particularly interested in making a successful impression on unacquainted peers. Thus, adolescents might manage their impression online by considering and curating the food messages they transmit to others.

While most studies based in social facilitation theory focuses on the means in which the presence of others influences behavior, researchers have claimed that individuals modify their behavior to that of others; that behavior is learned from the environment in a process of observational learning. This process is often referred to as social modeling (Bandura, 1977; Grusec, 1992). Online social modeling of food consumption has been observed

among children and adolescents. Bevelander et al. (2012) showed by means of computer choice task with food pictures, that the use of fictional peers amplified children's inclination to try unfamiliar foods. A review of social modeling studies regarding food choice found that there was near universal support that food selection are influenced by the behaviors of others (Cruwys, Bevelander, & Hermans, 2015). The authors noted that there is indication that social modeling happens both because a), individuals seek information about suitable behaviors, motivated by reducing uncertainty, and b), because individuals want to identify with others, driven by an affiliation motive.

Whereas research on social modeling focus on modifications in persons' behaviors during the presence of others, research in the field of impression management aims to understand peoples' motivations to behave when in the company of others (Salvy et al., 2012). Impression management is often used interchangeably with self-presentation, where an individual seeks to influence the perception of their own image (boyd, 2007). Kümpel Nørgaard et al. (2013) showed that adolescents purchase and consume snacks that support their self-image when socializing with other peers. Krämer and Winter's (2008) study indicated that self-efficacy with regard to impression management in a social networking site is strongly associated to the number of virtual friends, the level of profile detail, and the style of the profile photo. Eating less seems to be a way to demonstrate a good impression at any age, probably because obesity and overweight is socially stigmatized, and persons are inclined to associate negative characteristics (e.g., physically inactive, overeaters) with persons who eat large quantities of food (Vartanian, Herman, & Polivy, 2007). Nevertheless, significant exceptions do exist: as previously explained; food items have cultural and social implications, and particular types of foods (e.g. desirable food brands or unhealthy snack food) linked with social status may be consumed and presented to others. Researchers have primarily linked this to young individuals' inclination

to express a positive impression amongst peers, which is emphasized during adolescence when peer consent becomes progressively important (Roper & La Niece, 2009).

Normative and Social Network Theories

One way to assimilate the mechanisms of social influences of eating is to adhere to Herman et al.'s (2003) normative structure, accounting for the influences of others on eating behavior. According to Aronson et al. (2010), social norms are defined as the procedures within a group for the tolerable behaviors, values, and beliefs of its members. The normative model suggests that, in the company of appetizing food, and when absent of other constrictions, individuals are motivated to eat as much as possible and that the presence of others is what governs when consumption stops. Consequently, social norms mainly function as inhibitory mechanisms, signifying when people should stop eating if they want to be socially appropriate. There are indications that apparent peer norms (descriptive norms; e.g. what the person thinks important others do) are even stronger connected to adolescents' soft drink consumption than the actual behavior of the peer group (Perkins, Perkins, & Craig, 2010). Lally et al. (2011) also showed that descriptive norms were strongly correlated with consumption of fruit and vegetables, soft drinks, and unhealthy snacks. However, the study did not identify an association between injunctive norms (i.e. beliefs about how a person should behave) and dietary intake.

Adolescents are exposed to the food related norms and influences of peers in their extended online networks. Although adolescents will normally add friends and acquaintances as 'friends', they will also add people since it would be socially inelegant to decline friendship requests, because they make the adolescent seem cool, or merely because it would be fascinating to follow their uploads (boyd, 2007). Because 'friends' are displayed on the adolescents' online profile,

they also provide meaningful information about that person. This reflection is significant for food communication as eating is usually a highly communal experience (Delormier, Frohlich, & Potvin, 2009). When adolescents share photos of foods they experience, the photos also becomes a confirmation of the larger event experience with other individuals; they want people to know who they participated with. A desirable lifestyle therefore includes the opportunity to share exclusive foods via one's online social networks. Facebook users can for example see food-related pages that members of their online social network have endorsed (e.g. 'liked'), and also food content they post. This may establish social norms around certain foods high in social status.

Stok et al. (2013) investigated whether communicating health-promoting descriptive and injunctive norms influences adolescents' intended and actual fruit consumption. The researchers distributed booklets with informational text regarding the consumption of fruit and vegetables to the students. They found that booklets containing descriptive norms influenced consumption but not intentions. The researchers also found that the injunctive norms not only had no positive effect, but that they could potentially decrease fruit intake. The authors discussed that injunctive norms could lead persons to feel like they were being pushed in a certain track by the source distributing the norm, particularly when the norm was not in line with their personal beliefs. Conversely, the researchers thought that descriptive norms could motivate by indicating what would be effective and adaptive behavior in a particular situation.

The normative structure is particularly useful when interpreting recent evidence that obesity and obesogenic behaviors tend to cluster in adolescents' social networks (Salvy et al., 2012). Research conducted in the field of social psychology has showed that adolescents' consumption of snacks and soft drinks was related with their peers' intake (Wouters, Larsen, Kremers, Dagnelie, & Geenen, 2010). The researchers also found that the correlations between individual and peer snack intake was particularly

strong among boys and youths with lower body weights. Food intake is often underreported in adolescents as well as adults with obesity, compared with their normal weight peers. Bevelander et al. (2011) showed that not only are adolescents' influenced by their peers when it comes to consuming foods, teenagers also influence each other when it comes to food purchases; girls' higher calorie food purchases are correlated with their peers' food purchases. Since friends share their snacking behaviors, education and interventions need to address both the individual snacking practice as well as the social component of snacking.

FUTURE RESEARCH DIRECTIONS

Considering the widespread use of social media applications among adolescents, future experimental studies are needed to examine whether social media networks such as Instagram, blogs, and Facebook actually influence adolescents' food habits. Specifically, research is needed to explore how the content and delivery of information on social media appeals and engages adolescents, stimulates behavior change, sustains behavior change, and how social media impact obesity risks in adolescents. This literature review also emphasize that there are theoretical underpinnings that need to be explored and developed further, especially concerning their usability in social media studies involving adolescents.

CONCLUSION

This chapter employs different theoretical and analytic frameworks that suggest social media as an evolving setting for social influence on adolescents' dietary habits, which also have contiguous impacts on children's health risks such as obesity. Social modeling, normative theory, and network theory are all relevant frameworks that can be used to explore how social media influences adolescents' food practices.

KEY TERMS AND DEFINITIONS

Impression Management: Conscious or sub-conscious procedure in which adolescents attempt to influence the perceptions of themselves. This is done by regulating and adjusting information in social interaction.

Online Social Networks: Online services that permits individuals to construct a public or semi-public profile within a network, and specify other users with whom they share a connection.

Social Facilitation: A theory that suggests that there is an improvement in performance produced by the actual, imagined or implied presence of others.

Social Media: Umbrella term for Internet-based services and applications that permit its users to construct individual personal profiles, generate and access searchable online content (e.g., images, videos), form online connections with other users, and view these social connections.

Social Modeling: A theory that stipulates that we learn to imitate others by observing their behavior and that we learn to behave in certain ways by watching others do what they do.

Agent-Based Social Networks

INTRODUCTION

Social networking sites have deeply changed the face of the web in the last decade. Social web sites have attracted users with very weak interest in technology, including people that before the social networking revolution were not even regular users of other popular Internet services and computers in general (Stroud, 2008). The phenomenon is so widespread that many people started using social networking systems to ask questions directly to people instead of querying search engines (Morris et al., 2010) and in place of regular email. Moreover, some of the largest social networking sites constitute a separate and closed network (Sabbag, 2011). After the huge success of the early social networking systems, many other players came in the social networking market and nowadays hundreds of different social networking systems exist. Even if the social networking systems are greatly dissimilar in their user base and functionality, they are almost always centralized systems. The centralized nature allows a simple browser-based user experience and, moreover, many algorithms, e.g., friend suggestion, are far easier and more efficient to implement in this setting. However, such a solution has many drawbacks, e.g., lack of privacy, lack of anonymity, risks of censorship and operating costs. Therefore, a decentralized architecture may offer several advantages, but it may involve some security and design issues that are not present in

traditional social networks. This chapter has the goal of introducing social networks and how they can take advantages of a decentralized architecture and how the use of multi agent technologies help to cope with its security and design issues and, in addition, to support the creation of innovative services for its users.

BACKGROUND

Social networks can be defined as structures consisting of a finite set of actors and the relation or relations defined on them, where an actor is simply a discrete individual or a social unit (Wasserman & Faust, 1994). Social networking systems are implemented as web-sites allowing users to have a profile and managing their online social network, i.e., such systems allow them to: (i) construct a profile which represents them in the system; (ii) create a list of users with whom they share a connection and (iii) navigate their list of connections and that of their friends (Ellison, 2007).

Although we agree that self-presentation and social network management are extremely important and necessary components of a social networking system, we believe that the social networking revolution is far more related to the paradigm shift that transformed most people from mere consumers of information to full-fledged information producers. Most people create information which is essentially personal and, then, it

is mainly of interest for friends and acquaintances. Before the social web revolution such information used to be essentially lost in the web, while, nowadays social networking systems are able to deliver the information to the “right” people.

After the huge success of the early social networking systems, many other players came in the social networking market and nowadays hundreds of different social networking systems exist. Even if the social networking systems are greatly dissimilar in their user base and functionality, they are almost always centralized systems because of the access and implementation advantages.

A minor drawback is that scaling centralized systems to tens or hundreds of million of users is not an easy task. At any rate, we consider this drawback as a minor one, since the problem can be solved providing enough resources. However, the huge operative costs of supporting the infrastructure necessary to provide the service to millions of users can only be justified with robust business plans. While some social networking services have extremely differentiated business models (McGrath 2010), for most of them the primary source of income is advertisement and consequently they have a strong motive for: (i) using user provided data to increase performance for that purpose and (ii) even giving access to authorized commercial third parties to the raw data. This behavior poses serious threats to privacy and data protection issues, especially considering that there is no clear legislation on what uses of the user data are legitimate, and regarding the conditions for disclosing the data to third parties, especially when the subjects involved are from different countries.

Another problem is that social networking systems have terms of service that their users give to the system operators a non-exclusive, transferable, sub-licensable, royalty-free, worldwide license to the submitted content (Facebook, 2016; Twitter, 2016). Such terms are needed for legal reasons: in order to serve webpages containing the users’ data (e.g., their profile page) the service provider needs some rights over that data; it is nonetheless

true that users are essentially allowing the service providers to do with the data whatever they want for free. Moreover, most of the times, the users themselves have not easy and streamlined ways to obtain all the data they inserted in the system in a semantically meaningful or at least in a structured way; this (i) is a serious lock-in problem in its own right and (ii) hinders users’ trust in the platform. Most social networking platforms do not provide their users with easy and standard ways to export user submitted contents in a structured way. According to Fitzpatrick and Lueck (2010) this issue (i) is similar to a serious lock-in problem in its own right, and (ii) it hinders users’ trust in the platform.

The last problem with centralized social networking system is that service providers are in the position to effectively perform a-priori or a-posteriori censorship, or to disclose all the information they have, no matter how private, to other entities. They can perform such actions either motivated by selfish interests or forced under legal terms and other forms of pressure.

DECENTRALIZED SOCIAL NETWORKS

Peer-to-Peer (P2P) technologies are the most suitable mean to build decentralized social networks. In fact, P2P technologies allow the definition of open and decentralized overlay networks on top of the Internet that users can use for directly communicating to find and share resources, often music and movie files (Schollmeier, 2001). Such networks are one of the few largest distributed computing systems ever, and more surprisingly, they can run with great stability and resilient performance in face of possibly the most ferocious dynamics (Qiu & Srikant, 2004).

Thus, the use of P2P technologies for the development of social network is not only viable, but also highly desirable (Wang et al, 2006). First of all, P2P systems essentially achieve automatic resource scalability, in the sense that the avail-

ability of resources is proportional to the number of users. This property is especially desirable for media sharing social networking systems, considering the exceptionally high amount of resources needed. Secondly, the popularity over time of most content on such systems exhibits either a power-law or an exponential behavior and is consequently well suited for P2P distribution (Zink et al., 2009), possibly with fallback strategies for less popular content.

Regarding censorship issues, a P2P system essentially solves them by design. Without a central entity, nobody is in the position of censoring data systematically nor may be held legally responsible for the diffusion of censurable data: the sole owners and responsible of the data are the users themselves. Unfortunately, P2P systems, and especially Distributed Hash Table (DHT) based ones, may be still liable to attacks meant to disrupt the system functionality (Urdaneta et al., 2011), often based on the introduction of a large number of Sybil nodes and the diffusion of bogus information. However, the most popular DHT systems are significantly robust because of the high redundancy they achieve by using data replication and a redundant routing mechanism. Usually, the countermeasures are based on the embedding of the identity notion into the overlay level (Aiello & Ruffo, 2010), and on the use of some notion of “trust”, based on either certification authorities or some reputation mechanism (Aiello & Ruffo, 2012). Common consensus algorithms, including Byzantine agreement, have also been proposed and applied (Balfe et al., 2005; Anceaume et al, 2008).

Although peer-to-peer systems overcome the weakness of a single point of failure, there are some well-known and important vulnerabilities, including (i) Sybil attacks, or node insertion attacks, where multiple nodes are created in the network, each of them representing fictitious identities but all belonging to a single user; and (ii) publish attacks, based on index poisoning, where essentially some bogus content is deliberately spread to the index nodes responsible for other files or keywords. The presence of Sybil

nodes allows other attacks, e.g. routing attacks, eclipse attacks, storage attacks. Also publish attacks may exploit the presence of Sybil nodes, if available. Many of the proposed countermeasures to securing peer-to-peer networks are based on some notion of “trust” among peers. Depending on the approach they use to evaluate and manage trust relationships among peers, those countermeasures can be divided in two main groups: (i) credential and policy based, (ii) reputation based. Urdaneta et al. (2011) provide a detailed analysis of threats to DHTs, together with some proposed countermeasures. While underlining the existing vulnerability to Sybil attacks, authors conclude that “Current DHT deployments are not specifically designed to tolerate the presence of malicious nodes. However, most of them are based on Kademlia, which provides relative security by using data replication and a redundant routing mechanism similar to wide paths”.

Eventually, the lack of a central entity which has, or believes to have, interests in hindering interoperability (Shankland, 2011), creates the opportunity to design the system so that heterogeneous units can interoperate, typically providing a semantic common setting for the data.

Various solutions are being proposed to overcome the centralized architecture of the most widespread social networking platforms. Many of these proposals follow a federated approach, allowing users registered on a certain server to create relationships with users of other servers. Others are full-fledged peer-to-peer systems, usually based on a DHT.

Among the federated social networking systems, two of the best known are Diaspora (Bielenberg et al, 2012) and StatusNet (StatusNet, 2016). Diaspora servers communicate by means of an ad-hoc federation protocol and the standard Salmon protocol for comments. Users can (i) participate in the network by setting up their own server, which is named a “pod”, or (ii) exploit already existing pods. Using a number of existing protocols, StatusNet shows quite strong interoperability with other networks. With regards

to the completely distributed solutions, their origin can be traced back to Freenet (Charke et al., 2001), which is meant as a distributed, cooperative, uncensored and secure file system. It uses a “best-effort” unreliable routing algorithm to find content and namespaces, over both “Open-Net” and “DarkNet” connections. Various quite popular uncensored forums are built on Freenet, but they usually suffer a large amount of spam coming from anonymous sources. Similarly to other more recent systems.

Specifically in the field of social networking, various systems are being developed on the basis of peer-to-peer communications and DHT indexing. Among them, Maze (Chen et al., 2004), TRIBLER (Pouwelse et al., 2008), PeerSoN (Buchegger et al., 2009), Persona (Baden et al., 2009), Safebook (Cutillo et al., 2009) and DECENT (Jahid et al., 2012) are the most interesting.

Maze (Chen et al., 2004) supports a peer-to-peer social network through the use of some centralized services. It uses a ticketing server which issues tickets to all peers to identify them. This ticket is then served as a form of legitimate communication/transaction between peers. The ticket is valid for a single communication. For further communication, all peers need to contact the ticketing server for a ticket. Maze also uses another centralized server which, apart from holding a directory of peers, also checks online status of each of them.

TRIBLER (Pouwelse et al., 2008) is a P2P social-based file sharing network which is built on top of the Bittorrent protocol (Cohen, 2003). Tribler is based on the generation and maintenance of social networks in order to improve content discovery, searching and download performance. In particular, it proposes a decentralized recommendation mechanism based on standard collaborative filtering techniques and that takes advantage of the concepts of friends, friends-of-friends and tastes communities.

PeerSoN (Buchegger et al., 2009) is a system designed to provide encryption, decentralization and direct data exchange in the field of social
